39.6% of the students admitted that they had participated in the harassment of another student on several occasions, and 22.6% said this happened two or three times a month. When baiting, 26.4% of teens used abuse and neglect, 20.8% used physical force, and 37.7% mocked their victim's appearance. 15.1% of respondents spread false rumors about others once a week, and 9.4% ignored a classmate and excluded him from the joint activities several times a week.

The next stage of the study was to determine the relationship between indicators of bullying, empathy and aggression. For this purpose we used Pearson's correlation coefficient.

When a sample of 53 people the critical value of r with p 0,05 is equal to 0.27, and with p 0,01 is equal to 0.35. Based on these data, we checked the value of the Pearson's correlation coefficient, i.e., the accuracy of its difference from zero.

From the analysis of the Pearson's correlation coefficient, we found that there is a reliable indicator of a direct link between empathy and bullying ($r_{xy} = 0.48$) at a significance level of p 0.01, and a reliable feedback from indicators of physical aggression ($r_{xy} = -0.35$) at a significance level of p 001, indirect aggression ($r_{xy} = -0.32$) at a significance level of p 0,05, suspicion ($r_{xy} = -0.85$) at a significance level of p 001.

We found a significant direct relationship between indicators of bullying and indirect aggression ($r_{xy} = 0.4$) at a significance level of p 0.01, aggressiveness index ($r_{xy} = 0.31$) at a significance level of p 0.05, significant direct correlation with the index of irritability ($r_{xy} = -0.06$) at level of significance p 0.01. This suggests that the higher the bullying, the higher indirect aggression index, and the lower irritability and aggressiveness.

We also found a direct link between reliable indicators of physical and indirect aggression ($r_{xy} = 0.41$) at a significance level of p 0.01, indirect aggression and negativism ($r_{xy} = 0.28$) at a significance level of p 0.05.

A significant inverse relationship was found between rates of irritability and negativity ($r_{xy} = -0.29$) at a significance level of p 005. We identified a direct link between reliable indicators of negativity and resentment ($r_{xy} = 0.8$) at a significance level of p 0.05 and a significant inverse relationship between rates of negativity and aggressiveness index ($r_{xy} = -0.3$) at a significance level of p 0.05.

Thus, we found that the studied parameters are interconnected; our findings suggest that there is a link between indicators of bullying, empathy and aggression in younger teens.

As a result of the baseline experiment, we found that the high overall level of bullying in a group was dominant (54.7% - 29 adolescents), the overall average level was 35.9% (19 children), the low overall level was 9.4% (5 teens). Our findings suggested the need for remedial work to reduce bullying among teenagers.

On the basis of these results, we developed and implemented a program "Hand in Hand" aimed at prevention and psycho-pedagogical correction of bullying in school.

The goal of that program was prevention and psycho-pedagogical correction of bullying in school. Its objectives were to:

1. develop childrens' skills of analyzing actions and events for themselves, being aware of their relationship to the world, and being responsible for their actions;
2. develop readiness to help when necessary, ability to listen to others, and to empathize;
3. remove the fear of making an independent statement, and to develop communication skills;
4. develop the behavioral skills in conflict situations;
5. develop initiative and activity, feeling joy in sharing work and creativity.

With the help of correctional program "Hand in Hand" we created conditions for the prevention and psycho-pedagogical correction of bullying, leading to the solution of these problems.

Based on the objectives, we allocated five blocks that comprise the program:

Block 1: non-aggressive behavior formation;

Block 2: Generating unit of empathy and tolerance;

Block 3: Formation of self-confidence;

Block 4: Creating the readiness to overcome the formation of conflicts;

Block 5: Creativity formation.

Each unit includes 3-5 sessions, each of 45minutes. Classes are held in stages, following the block sequence. The principles guiding the development were to: achieve emotional comfort, activate the group members; building reliance on social and emotional experience of the group members; and providing an individual approach to every child.

For example, the first block which aimed to form non-aggressive behavior included the following classes:

Session 1. The goal is to familiarize the group members with the leader, to establish the rules of behavior, to create a working atmosphere, and to rally the group. The content included: the exercise "Business Card," the development of the rules for the group, the exercise "My personal place," the game "We count to twenty," and the exercise "Blind and guide," followed by respiratory relaxation and discussion.

Session 2. The goal is encourage the group to establish trusting relationships between the group members, and to identify aggressive behavior. The content included: the game "Message to yourself," the game "Bug," the exercise "Where should I sit?," The rôle-playing game "Fairy-tale Heroes," the exercise "Magic balls," and a concluding discussion.

Session 3. The goal is to respond to the emotions of the participants, to establish a trusting relationship, and to make the participants aware of their aggressiveness and non-constructiveness of such behavior. The content includes: "Greeting," the exercise "Expression of trust," a game "Pushing," the exercise "Recipe: how to make a child aggressive," ending with relaxation complex, and discussion.

Session 4. The goal is to teach the teenagers constructive behavioral reactions in a problem situation. The contents include: the game "Running Lights," the exercise "Drawing with a partner," a rôle-playing game, a relaxation exercise "Relaxing in a starfish position," and a discussion.

Session 5. The goal of the final session is to strengthen the trusting relationship between the group members, to teach the teenagers constructive behavioral reactions in a problem situation, and to develop a non-verbal ability to express emotions. The contents include: "Greeting," the exercise "Without Mask," the rôle-playing game "Aggressors" and "Victims," pantomime, relaxation exercise "The Rock," and a discussion.

Classes are organized so that every teenager "lives" different situations, determines his or her ability to support and recognize the merits of the other, to defend his own position, to organize himself and others, to be creative and to understand and accept each other.

The process for each class is as follows:

- The ritual greeting which helps to unite the group, and to create the atmosphere of trust and acceptance;
- Warm-up. This prepares the participants for productive group activities, allows them to establish contact, activates the group members, cheers them up, and remove the emotional excitement. The warm-up is carried out not only at the beginning of the classes, but also between individual exercises if the teacher identifies a need to somehow change the emotional state of the participants. The warm-up exercises are chosen to match the current status of the group and the objectives for future activities;
- The basic content of the lesson is a set of forms and methods of pedagogical influence aimed at the development of competences, inherent in each unit;
- Relaxation involves the removal of the psycho-emotional stress, which can occur when performing certain exercises;
- The discussion of the sessions concern an exchange of views and feelings about the classes.

We used also energizing exercises during classes. Participants periodically experience decreased energy in the course of group activity. The energizing exercises (a mobile game) can serve as means of overcoming the energy dip, helping to activate various analyzers and encouraging the different abilities of the teenagers.

During the training we used a number of psychotherapeutic methods:

1. "Self-disclosure," when teenagers share personal feelings and experiences;
2. "Advice - wish" – the doctrine of how to act in a given situation;
3. "Experience - Interpretation" – offers a new vision of life situations, based on theory or personal experience;

4. “Desensitization of fears” –the opportunity to reduce anxiety, worry, and tension in important situations;
5. “Emotional reflection” – “rejection” of negative emotions, that is, transferring them through game-playing and thus releasing past traumatic experiences.

During the implementation the leader’s position varies depending on the their rôle as the expert, informant, equal participant, and psychologist.

Different life situations were highlighted during the classes. They rôle-played them, discussed, and made appropriate conclusions. Through these situations, younger teens learn positive interaction with others and find their own ways of solving conflicts. At the beginning, some students showed aggression toward their classmates, often communicating in a raised voice. After a series of classes the behavior of these students changed; during the exercises they remained fairly calm and defended their points of view using arguments without resorting to insults to the interlocutor.

The key to this program is that it is not implemented with victims and offenders separately, but together. This allows them to find deep solutions to the issues of interaction in society and gain valuable experience of the study of their personality, habits, beliefs, and interpersonal skills. The program “Hand in Hand” helps teens to look at themselves through the eyes of others, to live through difficult life situations, which are modeled in the classroom, react and express their experiences, and discuss current issues. The improvements in the levels of empathic tendencies are shown in Table 2.

After the programme the average level of empathy dominated in the group. Children were more susceptible to others, more sensitive, responsive; and reacted emotionally to other people’s troubles and setbacks. The program has had a positive impact on the development of empathy in young adolescents.

Table 2. Empathetic tendencies in the control phase compared with baseline figures

Level	Range for boys	Range for girls	Number at this level	Percentage of sample at this level	Baseline percentage	Increase (decrease)
High	26-33	30-33	15	28.3%	15.1%	13.2%
Average	17-25	23-29	29	54.7%	28.3%	20.4%
Low	8-16	17-22	8	15.1%	47.2%	(32.1%)
Very low	0-16	0-7	1	1.9%	9.4%	(7.5%)

The parameters of aggressive reactions also decreased significantly; there was indirect aggression dominated in the range of mistrust and caution against people to the belief that other people plan and bring harm reduced to 8.1. Irritability or aggression, in a roundabout way directed at any person or at no direction reduced to 8.4.

Table 3 shows the reduction in dominant aggressive reactions after the control program.

After the control program the aggressiveness index in the group was 18.8%, while the index of hostility was 20.8% - a reduction in the earlier values.

After the experiment the largest proportion of the group, 49.1% (26 adolescents), showed an average level of bullying. These children note the presence of violence in school, experience negative emotions and have a desire to respond in the same way. Physical violence dominates.

Table 3. Dominant aggressive reactions at baseline and after the control program

Characteristic	% of participants	
	Before	After
I know what people are saying about me behind my back	52.8%	15.1%
I stay caution with people who treat me a little more friendly than I expect	60.4%	28.3%
I think people do not like me	62.3%	32.1%
I believe that many people envy me	49.1%	18.8%
I think I am laughed at	45.3%	35.9%
My principle is 'never trust strangers'	37.7%	18.8%
If I do not approve of my friends' behaviour then I let them feel it	41.5%	9.4%
I often do not agree with people	34%	28.3%
I cannot resist a dispute if people do not agree with me	49.1%	28.3%
I require people to respect me	67.9%	15.1%
If someone annoys me I am ready to say what I think	77.4%	28.3%
When someone cries I start screaming response	73.6%	49.1%
I swear only in anger	32.1%	15.1%
I often threaten people, although I am not going to carry out the threat	45.3%	9.4%
I often raise my voice in a dispute	71.7%	18.8%
I do not always get what I am entitled to	86.8%	22.6%
I am almost always able to take advantage of favourable circumstances	88.7%	28.3%
I am a little distressed by my fate	39.6%	24.5%
I meet someone I do not like almost every week	83.0%	17.0%
I am sometimes consumed with envy although I do not show it	30.2%	18.8%
If everyone knew what I felt they would think that I am not easy to get on with	45.3%	26.4%
I sometimes feel that life treats me unfairly	71.7%	30.2%
I have experience pain and remorse when I have deceived someone	49.1%	18.8%
I sometimes have thoughts (about aggression) of which I am ashamed	37.7%	17.0%
I am upset that I do so little for my parents	32.1%	15.1%
I do many things that I later regret	28.3%	15.1%
I am distressed by failure	43.4%	18.8%
I feel moral qualms when I do wrong	45.3%	17.0%

Low level of bullying in the group after the experiment was found in 26.4% (14 adolescents).; This low emotional atmosphere is characterized by stability, the lack of physical and mental violence, and the absence of negative emotions.

There was a high level of bullying after the experiment was found in 24.5% or 13 adolescents. Here children point out the presence of violence in schools with a variety of bullying types and negative emotions. They experience fear, hatred, anger, horror, depression and apathy. Children also note the presence of physical and mental violence.

After the program 32.1% of the surveyed children believed that the problem of school violence does exist. Among the most common forms of violence there is still rudeness (52.8%) and mockery (49.1%), while among the less common there is deliberate destruction of another's property (9.4%), isolation (5.7%), and pushing down stairs (1.9%).

45.3% of children have a desire to respond in the same way. As for the children's sense of security in school, 49.1% answered that it depended of circumstances, and 50.9% felt totally secure. For psychological violence, 43.4% of students experienced it once or twice, and 22.6% experienced it once a month., 60.4% of respondents experienced psychological violence for themselves several times a month, 24.5% once a month and 15.1% experienced it once a week.

During that half-year 18.8% of children said that they were subjected to harassment once a week, and 32.1% experienced it several times over the same period. 15.1% did not know why they were bullied by other students. Others were more specific: 5.6% believed that it was due

to the fact that they were ignored and the teacher liked them more, 13.6% thought it was because they often quarrelled with others. 14.6% of the bullied pupils pretended that nothing happened, 18.8% avoided places where it occurred, 22.6% did not talk to anyone, and 19.4% were trying to explain that one cannot act this way. Among the methods used by the students to solve the problem of harassment, were opposition (17%), talking with the teachers (12.7%) and talking about it with parents (9.4%).

45.3% of students had witnessed bullying in the classroom. Of these 63.2% of them tried to help the victim, 18.5% did not do anything, (although they had a desire to help), and 18.3% did not do anything, as they decided that it was none of their business. 26.4% of the students admitted that they had participated in the harassment of another student several times, and 18.8% took part two or three times a month. Forms of baiting involved ignoring (26.4%), and spreading false rumors (17%). This was a frequent occurrence with 9.4% of respondents ridiculed and insulted once a week.

Table 4. Average levels of bullying

Level	Baseline	After program	Change
High	54.7%	28.3%	26.4% decrease
Average	35.9%	37.7% (20 children)	Dominant level
Low	9.4%	34.0%	26.4% increase

The analysis showed that the level of bullying in a group of younger teenagers exhibited a number of changes. High levels decreased from 49.1% to 24.5% (24.6% change), average levels rose from 32.1% to 49.1% (an increase of 17%), while the low level increased from 18.8% to 26.4% (a 7.6% change).

The overall impact of the experiments are shown in table 3 and demonstrate the effectiveness of the program of psycho-pedagogical correction of bullying in school “Hand in Hand.”

The Student’s t-test was used to confirm the results of the study. Differences in average $\bar{x}_{cr1}$ and $\bar{x}_{cr2}$ considered reliable if the empirical value of the Student’s t-test exceeds the critical value of t_{cr} . It is located in the tables of critical values of the Student’s t-test depending on the number of degrees of freedom. The number of degrees of freedom in the case definition for dependent samples t-test will be equal to $n - 1$.

In this case, for $v = 53$ critical values will be equal to: $t_{cr} = 2$ (at $p = 0.05$); $t_{cr} = 2.67$ (at $p = 0.01$). As a result of the Student’s t-test, we obtained the following data: the difference between the mean values of empathy before the experiment and after the event is valid since $t_{th} > t_{cr}$. ($t_{th} = -2.7$) at $p = 0.01$; the difference between the mean values of bullying before the experiment and after the event is valid since $t_{th} > t_{cr}$. ($t_{th} = 13.1$) at $p = 0.01$; the differences between the mean values of the overall index of bullying before the experiment and after the event is valid since $t_{th} > t_{cr}$. ($t_{th} = 4.9$) at $p = 0.01$. By all accounts we accept the hypothesis H1, that is, the identified differences in the studied parameters before and after the experiment, are authentic.

CONCLUSION

The study of younger teenagers showed that the use of the program “Hand in Hand” using literature and rôle-play games, aimed at the prevention and psycho-pedagogical correction of bullying, is effective. The study confirmed the hypothesis, that the effectiveness of prevention and psycho-pedagogical correction of bullying among young adolescents would benefit if it is based on the essential characteristics of the concepts of “bullying” and its structure, and takes into account the age-related aspects of the manifestations of bullying in early adolescence; These data were confirmed by statistical analysis and, in particular, the Student t-criterion.

ACKNOWLEDGMENTS

The work was carried out under the Russian Government Program of Competitive Growth of Kazan Federal University

Chapter 40

FRAMING SCHOOL BULLYING AS REFLECTION OF DETERIORATING BASOTHO MORAL PRINCIPLES

Paseka Andrew Mosia (D.Ed.)

Senior lecturer, National University of Lesotho, Lesotho

ABSTRACT

Bullying is globally perceived as a demonstration of deviant behaviour and a thorn to children who become victims, as well as parents who have to nurse the subsequent emotional and physical scars. If it is generally agreed that bullying demonstrates unbecoming behaviour, it remains a question as to why is it this difficult for education systems to put an end to it. This paper explores literature on contexts within which bullying has been documented, interrogates whether bullying is influenced by any gender dynamics, and crucially reflects on the reaction of key stakeholders within the education system, towards eliminating it. The paper argues that bullying as an antisocial behaviour does not resonate with being African, and in particular, deviates from Basotho as a people, known for mutual interdependence and hospitality to others. Some models on psychosocial development are used to explain how the contexts of school bullying in Lesotho could represent slips in the broader social values of *ubuntu/botho*, and thus merit a wider reflection on improving society's moral standards. The paper concludes by suggesting how *ubuntu/botho* can work as the best principle for addressing school bullying, and violence generally.

Keywords: bullying, deviant behaviour, morality, mutual interdependence, *ubuntu*

INTRODUCTION

The advent of colonisation in Africa created a permanent destruction to her outlook onto the world, where her people had an interdependent self-concept, nurtured by principles of love and empathy. The intruder was in pursuit of greed underpinned by individualistic conceptions. A western ethos promoted competition and private ownership, and colonialists used this to divide Africans along ethnic lines, igniting furious hostilities over territories they had otherwise

shared over centuries. This offended the commonly held view of African people as living in groups that are naturally communal and cooperative. With it, colonisation brought industrialisation, which broke normal social structures of communal living, and forced some people to migrate to newly built towns to work for the capitalists. In reflecting about how the Awori people of Ogun State in Nigeria have changed, Wahab, Odunsi and Ajiboye (2012) note that rapid urbanisation and industrialisation forced people to live as nuclear families, away from extended members thus breaking the socialisation according to which moral principles were easily shared among community members. Reflecting on the changes that built the modern society may lead to a more nuanced understanding of how Africa shifted from its roots, and how her people may be said to live in moral vacuum brought about by such acculturation. Against this background, I intend to describe school violence, and specifically bullying, as one among several examples of the erosion and extinction of *ubuntu/botho* characteristics of the Basotho, a nation found in the Southern part of Africa.

SCHOOL VIOLENCE, AS TYPIFIED BY BULLYING

This paper discusses bullying within the broad scope of school violence, because it would be futile to ignore other forms of violence such as corporal punishment, sexual violence etc. while there is confluence between these. It would also be unjustifiable to expect a teacher who believes in violence to solve misunderstandings with students, inadequate academic effort, and low motivation from learners, through inflicting pain than applying non-coercive measures. Young children look up to teachers for guidance, and many teachers are old enough to be parents to the learners, so teachers' influence on learners' psychosocial development is immeasurable. As such, bullying is but an example of many unbecoming behavioural attributes displayed by school community members to one another.

In defining school violence, De Wet (2007a:78) says it is "the intentional use of physical and physiological force or power that may negatively affect school's educational mission or climate conducive to teaching and learning." It is a broad concept that encompasses the use of undue force within an education system by students to their peers or teachers, or by teachers against each other or students, using corporal punishment as a form of discipline leading to physical and emotional pain for its victims. Evident in this definition is that the violence in overt or covert form has no place within an education system, as it makes the atmosphere unhealthy for teaching and learning. Bullying, though it may affect learners as groups, is mostly an interpersonal violence that negatively affects physical, social and psychological development of the victims (De Wet 2007b; Mosia 2015). It differs from a once-off incidence of violent behaviour or interpersonal conflict, but depicts aggression that is intentional and committed frequently over time (Motsei & Nkomo 2016). Letšopha and Jacobs (2017:87) describe it as "willful, and mostly repetitive, as well as there always being power differential" between bullies and their victims. The violence is committed by those who are normally physically superior, and more powerful than victims who are usually defenseless and submissive (Ngakane, Muthukrishna & Ngcobo 2012; Mosia 2015).

While most literature focuses on victims of bullying in terms of their characteristic features which render them vulnerable, their coping mechanisms etc. some literature describe bullies as equal victims of psychological deficiencies such as poor self-concept and academic

weaknesses (Mosia 2015). Generally, research evidence supports the notion that bullying amongst learners demonstrates academic and social skills deficits, as bullies usually lack critical thinking and reasoning skills vital for negotiating healthy interpersonal relationships (Ngakane et al. 2012; Letšopha & Jacobs 2017). Similarly, perpetrators of schools violence, such as teachers who use corporal punishment on learners, seem to demonstrate deficient psychosocial skills in managing abnormal behaviours (Letšopha & Jacobs 2017). Teachers' behaviour, in active use of violent disciplinary measures or passively neglecting incidents of bullying, acts as reinforcement to school violence generally.

School violence can also take different and gendered formats. In trying to understand the nuances of school violence, some writers argue that school violence cannot generally be understood in isolation from the broader social context within which it occurs (Motsei & Nkomo 2016). School violence in Lesotho takes various forms of gender dynamics. Morojele (2011) reflects on how, as he grew up, boys had to fit certain gender stereotypes within which they had to conform or be ridiculed. Boys were pressured to comply with "Characteristics of hegemonic masculinities included competitiveness, being anti-school, being rough and tough, proposing love to girls, subordinating boys who are regarded as weak" (Morojele 2011:680). Citing Morahanye's (2004) master's study on gender stereotyping, De Wet (2007b) argues that certain violent behaviours on the part of men against women in Lesotho results from these patriarchal tendencies that promote male dominance. It becomes inevitable that some bullying habits develop out of misguided cultural undertones. Subsequently, sexual abuse as another type of violence results from male assertions of this perceived entitlement over women. Analysed closely, Bhana (2005 in Ngakane, Muthukrishna & Ngcobo 2012) notes that violence that leads to sexual abuse of women in schools can be explained by unhealthy social constructions of masculinity and femininity.

Additionally, there is research that demonstrates that teachers also apply corporal punishment distinctively between boys and girls, with boys receiving harsher punishment than girls (Ngakane et al. 2012; RTI International 2013). Essentially, in societies where gender stereotypes are foregrounded, it may not be difficult for teachers to identify typical victims of bullying. For example, Makafane and Khalanyane (2018) note, "gays, lesbians and people with queer sexuality are more prone to being bullied", because bullies would feel they must be punished for not fitting neatly within conventional gender categories. However, great attention must be placed on female victims of school violence, as they are more prone to verbal, social and psychological violence from other girls (Mosia 2015), and frequently fall victims of sexual violence from peers and teachers (De Wet 2007b). In its various forms, school violence signals grave moral degeneration of a society, of which a school is but a microcosm (Ngakane et al. 2012).

PREVALENCE OF SCHOOL BULLYING IN LESOTHO

A number of studies describe bullying in Lesotho schools as posing problems to conducive learning environment and learners' safety. Some studies highlight the indecisiveness of teachers in addressing bullying as one of its enablers. Ngakane et al. (2012) says school boys at secondary level use violence for various reasons, such as exercising power and solving conflicts. For example, in one incident, boys collectively fought learners from another school

because they lost a soccer match, they also went on strike to force the principal to change the menu in the school kitchen; while in yet another incident, older boarding school boys forced juniors to wash their clothes after school where upon refusal, victims were beaten. Letšopha and Jacobs (2017) note that relational violence is mostly used by girls in schools to make their victims feel socially unwanted. For example, public humiliation of new learners by their seniors is common in many schools. Additionally, Mosia (2015) describes situations where ill-treatment of junior students at one college culminated in criminal behaviours, committed unceasingly. For example, one student was killed at Lerotholi Polytechnic in 2009, while two were killed in February 2012 in the same college in what students referred to as initiation rites. He also gives examples of incidents of students stabbing victims to death at secondary school level. An article in one of the local newspapers, the Lesotho Times (4 June 2015), describes how many of the bullying incidences in schools around the country fit the punishable criminal offences. The paper cites section 8 the Constitution of Lesotho 1993 and various sections of the Penal Code Act, 2010 as providing grounds for the bullies to be prosecuted. This justifies my argument that bullying in any form cannot be tolerated, because it offends social cohesion in society and breaks the spirit of *botho*, which binds communities as interdependent.

Generally, literature shows teachers as constantly modelling violence in their day-to-day interactions with learners, by the use of corporal punishment to manage their behaviour. For example, Ngakane et al. (2012) record that some teachers even punish students for poor academic performance. It is morally wrong for teachers to punish learners who demonstrate academic challenges, because learning problems can also result from teachers' inability to use appropriate teaching methods, lack of relevant teaching and learning resources etc. however, many studies give accounts of this kind of gruesome display of violence (see Monyooe 1983, 1986, 1996; De Wet 2006, 2007b, Ngakane et al. 2012; Matheolane & Makura 2014). Some writers go to the extent of claiming that corporal punishment is permissible in Lesotho, and is popular in all types of schools, church, community, and government schools (De Wet 2007b; Jacobs, De Wet & Ferreira 2013). Teachers are said to espouse an authoritarian discipline typical of the Christian dogmatism, and masculinity in patriarchal societies such as Lesotho (Jacobs, De Wet & Ferreira 2013). However, violence of any kind has always been outlawed by the Constitution of Lesotho section 8(1) of which reads, "No person shall be subjected to torture or to inhuman or degrading punishment or other treatment" (Kingdom of Lesotho 1993). This clearly demonstrates that Lesotho and the Basotho do not endorse the embodiment of violence as a form of acceptance in dealing with each other as humans. The Enactment of the Education Act 2010 was only the operationalisation, in schools, of an existing national policy on violence. Point 5 of the outline reads, "The Bill abolishes corporal punishment at schools in accordance with section 8 of the Constitution..." (Kingdom of Lesotho 2010).

It should therefore be lamented that teachers seem to contribute immensely to this scourge as passive or active reinforcement agent. Mosia (2015) observes that most incidents of bullying happen in class where teachers are supposed to control learners' behaviour, but fail to do so. Though teachers are aware of many incidents of violence, they ignore them (Beninger 2013), the bullies feel empowered, and victims accept violence as part of mandated reality. On a different note, De Wet (2006) also notes that in Lesotho, learners assaulting teachers is not uncommon, but is quick to indicate that teachers are to blame for using learners to commit acts of violence against colleagues in order to settle interpersonal grudges, or to unseat a principal whose leadership they oppose. The author of this paper was a victim of students' violent aggression, which remains inexplicable to date, where at school in 2004 four Grade 12 students

were given timeout as a result of indiscipline. It is not clear how they decided within 40 minutes of their stay outside class to throw stones at me with subsequent grievous injuries. This depicts poor morals and unethical conduct that may or may have not been influenced by teachers, my colleagues, who are supposed to show learners how to behave humanely and coexist with other members of society. On a different note, Beninger (2013) describes situations where teachers commit acts of sexual violence against young girls, either promising them higher marks, or money if victim come from underprivileged homes. Further, while Lefoka (1997) thinks teachers' sexual abuse and misconduct against their learners is abhorrent, she blames the Lesotho Teaching Service Commission for its incompetence in dealing decisively with the scourge and holding teachers accountable for moral decay in the profession. Thus, it is legitimate to conclude that such unethical behaviour of teachers undermines their moral obligation to protect learners' interest. It is evidence of a society that has completely lost its identity, and the moral fabric for which its citizens are known.

Violence of any type which is allowed to go unabated creates unsafe school environments, and is an impediment to the true purpose of education. A safe school environment is the one that complies with national as well as international policies, such as the United Nations Conventions of the Rights of the Child to promote basic human rights such as the right to life, human dignity, security etc. (De Wet 2007a). Lesotho obviously has policies that prevent the use of violence in schools, but teachers and some students continue doing so without control. Through the use of corporal punishment, teachers unwittingly promote bullying in schools, where children learn that the use of force and one's power is acceptable to solve interpersonal differences (De Wet 2007b; Ngatane et al. 2012; Mosia 2015). By itself, violence results from learners' poor problem-solving skills, where bullies use it to solve problems that could easily be addressed through communication (Ngatane et al. 2012). Against this background, this paper intends to argue that behaviour displayed by teachers either through corporal punishment, sexual abuse of learners, incitement of learners to be violent, or the display of bullying behaviour by one learner to another offends the principle of *ubuntu/botho* that typifies the heritage of Basotho as a people.

UBUNTU/BOTHO: AN AFRICAN MORAL ETHIC

Ubuntu/botho, a term expressed here in both isiZulu and SeSotho, is a proverbial expression found in many languages of countries in Sub-Saharan Africa, and expresses a conception of desirable human attributes. It is the expression of human existence that is communal and relational, and different from the Western individualistic outlook on life (Le Grange 2012a). For example, in expressing how the Gikuyu people ought to conduct their lives, the former Kenyan president Jomo Kenyatta once said:

According to Gikuyu way of thinking, nobody is an isolated individual. Or rather, his uniqueness is a secondary fact about him: first and foremost he is several people's relative and several people's contemporary. His life is founded on this fact spiritually and economically, just as much as biologically; the work he does every day is determined by it, and it is the basis of his sense of moral responsibility and social obligation. His personal needs, physical and psychological, are satisfied incidentally while he plays his part as member of a family group, and cannot be fully satisfied in any other way.

The speech depicts an African view of existence in which an individual is defined within the context of others' existence. There is no self without the other as self is defined in relations to the other.

In reflecting on this perspective of life, African Philosophers such as Mbiti (1969 in Letseka M.M. 2013) describe a traditional African's life as one characterised by interdependence, where one lives in and for his family, as well as the community at large. This African philosophy is expressed as, *umuntu ngumuntu ngabantu* (in the Nguni languages of Southern Africa) or *motho ke motho ka batho* (in Sotho languages) and translated imperfectly into English as, "a person is a person by association with other persons" (Letseka M.M. 2013:747). Through the lens of this principle, it becomes odd to think that bullying is part of the African culture; no one can build others by fighting them. Reiterating this proverbial expression, Mbiti, famously quoted the expression "I am because we are; and since we are, therefore I am" (Mbiti 1989:141). This illustrates the view that an African exists in company of, rather than in isolation from others. The philosophy describes the art being or personhood as one achieved by complementing others and doing well for the community. To this end, Majeed (2017:35) writes, "A person has the tendency to act morally and has the general social good or the community's interest in mind. The community requires goodness of its members and the individual provides that." Therefore, if *ubuntu* is the guiding moral ethic of Africa and her people, the vast documented acts of school violence in Lesotho and elsewhere, committed by teachers and learners alike, stand in sharp contrast to this philosophy and attest to moral degeneration resulting from "colonialism, modern science and technology, [and] enlightenment humanism..." (Le Grange 2012b:63). It is apparent that post-colonial Africa has lost her moral campus and Lesotho is no exception.

CONTEXTUALIZING *UBUNTU/BOTHO* WITHIN BASOTHO CULTURE

Lesotho is a small country in Southern Africa of about 30,000 square kilometres with a total population of 2,007,201 (Kingdom of Lesotho 2016). It was a British protectorate for a century and was allowed to form as a country, due to its social, cultural and linguistic unity (Beiroth 2017). Beiroth, in her master's study, gives a critical analysis of the moral values that a great number of Basotho, especially those living in towns, have lost through acculturation. They used to be a unified and compassionate society. It is the unity that is mostly ascribed to ethical leadership of its founder, King Moshoeshoe I (henceforth Moshoeshoe), who "prove[d] that diversity can be a binding attribute, in an environment in which it could otherwise be expected to be divisive" (Mofuoa 2015:24). Moshoeshoe is praised for being an embodiment many positive attributes that include, "the reality of *botho*, meaning relatedness and community, as well as exemplifying both *seriti* (vitality) and *hlomphe* (respect)" (Prozesky 2016:8). As Mofuoa (2015) notes, Moshoeshoe ruled through seeking consensus from opposing sides, and never retaliated against people who aggrieved the Kingdom when it was fashionable for kings to use military power enhance their leadership. In citing Nussbaum (2003), Letseka M. (2013:339) describes *botho* as an expression of "compassion, reciprocity, dignity, harmony and humanity", which are attributes that are well-documented to have characterised the entire leadership of King Moshoeshoe.

However, these admirable attributes of a society at peace with itself and neighbours have suffered cultural erosion due the carelessness and lassitude of its custodian (Wahab et al. 2012). It is therefore not surprising that Letseka M. (2013) reports social ills rampant in schools and many social spaces, which undermine social morality of the Basotho as reported in various media platforms. The scourge of social violence in our communities insults the basic attribute of Basotho as a society that lived communally and shared itself compassionately. Despite the concern, Beiroth (2017) notes that until now, it is common that the Basotho in rural settings still know each other intimately, though not living in the same villages, and continue communal living. She also cites typical reconciliatory overtones in words such as '*khotso*' (peace) used for greetings, followed by elaborate questions regarding one's wellness, along with that of family members. Similarly, Seema (2012:130, 133) quotes famous Basotho proverbs such as, *Bana ba motho ba kgaolelana hlooho ya tsie* (children of the same family share the head of a locust), which describes the hospitable character of Basotho as a nation. The word family in this instance extends beyond ones blood relatives, to describe Basotho's commitment to live communally. These are values passed from generation to generation, from the time of chief Mohlomi to King Moshoeshe, and are understood to sustain the Basotho. The communities share the memorable attributes of a Basotho society that lives in peace with itself (Letseka M. 2013). It is against this background that the education system in Lesotho must be redirected to adopt *botho* as a moral principle and guide.

MORAL EDUCATION AS REMEDY FOR SCHOOL VIOLENCE (BULLYING)

This paper has established that various forms of violence exist in Lesotho schools. The extent of the challenge is exacerbated by poor leadership from teachers, who must hold the moral campus. Teachers and learners alike mindlessly commit acts of terror that make schools unsafe for learning. Schools in Lesotho, though guided by the Education Act of 2010, which abolishes corporal punishment, have not established localised policies to prevent and regulate bullying (Mosia 2015). Essentially, schools are built in communities from which both teachers and learners come, and these social ills cannot be said to originate from within the education system. As such, an intervention for school violence cannot be effective without dealing with the source of this moral decay. When speaking of moral education, Letseka M. (2013) emphasises that education is not limited to formal education within school setting, but how society engages with itself in shaping its worldview. In this particular case, the rot is deeper than the education system as represented by teachers who, as parents away from home, their morality is put into question. Thus, this paper calls for a national '*pitso*' (public gathering), where traditional leaders, politicians, and educational leaders might interrogate the source of this moral decay, so as to retrace steps to where Basotho lost the principle of *botho*. It is within this framework that communities could be sensitised, and teachers retrained on reconstructing the Basotho moral fabric. At the risk of sounding pessimistic, I think we cannot deal with school violence without addressing the broader moral decay evident in our communities and amongst our children, who grow up absorbing effortlessly.

Chapter 41

DISCRIMINATION AND BULLYING IN AN ELEMENTARY SCHOOL IN JAVA, INDONESIA

Margaret E. Shore, PhD and Riana Cahyani

Sekolahku-MySchool, UPP, Yogyakarta, Java

ABSTRACT

This chapter outlines an exploratory study of the extent of gender based bullying occurring in an inclusive elementary school, Sekolahku-MySchool (SMS), in Yogyakarta, Indonesia. In this qualitative study, two major issues facing education in Indonesia today, discrimination and bullying towards women, are addressed.

Questionnaires and in-depth interviews were conducted with thirty-three (33) female students aged 7–12 years in Elementary classes 1 to 6, who attended a Javanese Indonesian school. The interview questions identified girls who commenced SMS in their pre-Elementary classes and those who transferred into SMS from other schools into the Elementary classes. The latter group of girls appeared to be victims of discrimination or bullying, and, in two cases the victims became bullies themselves. The two groups' Stages of Play and feelings about Classroom Rules together with their experiences and responses to school bullying provides rich data that indicates that bullying still exists despite a Year-long, school wide Anti-Bullying program. Anecdotal evidence, observations and interviews with the Head of School, a female teacher and thirty-three (33) girls, offer a fascinating insight of how female gender roles are firmly entrenched in a traditional society, and how bullying starts, continues and escalates. A case study of one girl, who emanated from a different culture, provides a sequence of events that triggered the bullying for her, and the school's response to it.

Keywords: gender equity, traditional roles, anti-bullying, cultural differences, cultural change.

1. INTRODUCTION

Indonesia is a fascinating country of seventeen thousand (17,000) unique islands, with over two hundred and sixty-eight million (268,000,000) people and three hundred (300) distinct

ethnic and linguistic groups. The seven hundred (700) languages (World Population Review, 2018) derived from centuries of inherited traditions and values, were influenced by the four hundred (400) years of colonization by the Dutch and the aggressive invasion by the Japanese in 1942 (Wikipedia, 2019). Two subsequent dictatorships, from 1946 onwards brought further subjection to the Indonesian peoples and it was only in 1998 when University student activists contributed to the downfall of the then President, Suharto, that democratic elections were held.

Since 1998, when Indonesians declared they wanted to move towards democracy, this freedom was heralded by 4 changes of presidency in 6 years creating a rather tumultuous society that occasionally broke out into mayhem and hysteria. President Bambang Yudhoyono, a former general in the Indonesian Army, brought back a semblance of public order with his progressive rule towards a Democratic State during his period of Presidency, 2004-2014. During the last 5 years a young business man turned politician, President Joko Widodo has focused on building the sprawling country's infrastructure to cope with the growing mobility of the rapidly developing middle class.

Now, with the fourth largest population in the world, Indonesia is ranked number sixty-two (62) out of seventy-two (72) countries in the PISA educational ranking (OECD, 2015-2016). The Indonesian government has long recognized this educational shortcoming and actively sought new methods and ideas to ameliorate the situation. New curricula, new teacher incentives and new methods, many with International Aid importing Westernized solutions delivered by Western specialists to Asian challenges, have only touched the surface of these problems (Shore, 2018). New education strategies, new techniques and new technology have been introduced, with the two former initiatives disappearing as fast as the many highly paid consultants who have met their respective Embassies' Training Aid criteria and outcomes (Shore, 2006). While new technology has exploded in Indonesia, many of the traditional cultures and values are still only slightly touched by progressive educational strategies and westernized techniques.

1.1. Sekolahku-MySchool

The inclusive Play-group, Kindergarten and Elementary school, SMS, is located in a Javanese village, Ngaglik, a sub-urban neighbourhood of Yogyakarta, surrounded by rice *paddies* (fields) and other farming of agricultural products. SMS buildings and grounds reflect the Javanese history and traditions of sustainable agriculture and SMS works to maintain the Javanese cultural traditions and language. At elementary level the school accepts children aged 7-13 years and divides these into 6 classes, grade 1 to grade 6. There are 218 children attending SMS, 92 in Elementary, with a total of 45 staff and teachers, 12 of whom are in Elementary.

A *Yayasan*, the governing body is responsible to the parents' committee for the overall management, the quality of the curriculum and programs and the day-to-day operations. The parents' committee is mostly comprised of well-educated parents, many of whom have studied at Colleges or Universities.

SMS has 2 education consultants who are responsible for developing quality programs in the school. One consultant is an overseas volunteer education expert who has led the development of the alternative education system in SMS for 15 years. The other consultant is an Indonesian education practitioner with a psychology background who, during the last 13 years, has focused on developing the Anti-Bullying curriculum in SMS.

The Elementary principal has worked at SMS for 13 years. She has had experience in teaching all age groups in inclusive classes with children of various cultural backgrounds. Many of these children have required extra assistance with their developmental problems. These problems include being on the Autism spectrum, being a slow learner, suffering from Attention Deficit Disorder (ADD) or other Psychological, Physical or Emotional interruptions to their growth and development.

An Elementary teacher from grade 5-6¹ with more than 9 years' experience in Inclusive classrooms was interviewed to obtain a description of the case-study child's behaviour in the classroom as well as the chronology of the reported cases of bullying.

1.2. Purpose of the Study

This exploratory research seeks to identify the incidence of discrimination and bullying by and to girls occurring across SMS Elementary School, Year 1 to Year 6. The study uses the consultants' observations and discussions with the teacher, the girls' own perceived and documented incidences of bullying they have experienced or seen at Sekolahku-MySchool or previous schools. Interviews took place with two groups of girls between the ages of 6.7 and 12 years of age from the Elementary Grades 1 – 6. Group 1 have attended SMS since Play Group and/or Kindergarten, and a second group, Group 2, of girls entered the school in various Elementary classes.

1.3. The Role of Females in Indonesia

Marpinjun and Ramsey (2017:158) commented on the difficulty of changing cultural mores and traditions in their Chapter on Feminism and Early Childhood Education in Indonesia following a Gender Equity workshop they held to a group of female early childhood teachers. During workshop-activities almost all the participants voiced how "...gender inequity and rigid roles had limited their lives, and been the source of considerable pain..." (Marpinjun and Ramsey, 2017:158). In further activities participants depicted men's work as "...different types of jobs and sport...", whereas female activities included only "...domestic chores, such as cleaning, cooking, sewing and shopping." (Marpinjun and Ramsey, 2017:158).

Saptari (2017), a *perempuan* (Indonesian woman) art curator in Melbourne, Australia expressed these sentiments eloquently when she stated "Because of the complex meeting of traditional and modern values, Indonesian women have to continually fight to achieve sovereign rights that many women in other parts of the world now take for granted, ...". "(Its) important for us to share these voices and unheard stories so outsiders can appreciate the many cultural complications facing Indonesian women." (Saptari, 2017:1). These examples illustrate how traditional values persist even in the face of contradictory evidence, impacting informally on the way of life in the homes and villages of Indonesia, and formally in the workplaces and in the schools.

¹ Grade 5-6: Integrated Class.

That the role of women is as housewives and mothers was publicly endorsed by the first Indonesian President, Soekarno after *merdeka*² (1945-1965). This president reinforced the *status quo* of the woman's role as in the home. In 1964, the Soekarno Government decreed that Raden Adjeng Kartini (1879-1904), the intelligent and highly educated daughter of a Regency Chief of Jepara from an aristocratic Javanese family, was to be celebrated throughout Indonesia as a National Hero of Independence, a symbol of femininity and motherhood. She had been instrumental in advocating for girls receiving an education and for women having equal opportunities with men: She organized and taught in the first girls' school at Bulu, Rembang in Java. Kartini Day is now commemorated yearly by children wearing traditional feminine clothing in schools and performing activities related to femininity. Adults hold fashion shows and cooking competitions, showing a model of motherhood to which all girls should aspire, totally ignoring Kartini's academic achievements (Nugraha, E., 2018).

Indonesia is known for its patriarchal system, especially in Javanese society which has certain restrictions in gender relations that show the position and role of men as more dominant than women. The dual role of women is often denied, because of the patriarchal ideology that divides public space for men and private space for women (Handayani and Novianto, 2004). In Javanese society the woman's role is known as *kanca wingking*³, a term describing the function of women as people who are behind, and not visible. This is despite the fact that many Javanese women in general have a dual role, both public and domestic. It is the Javanese women who are the ones to wake up the earliest and retire to sleep the latest. Throughout the day they are busy taking care of the household, serving the husband and, not infrequently, still have to make a living for the family (Cahyani, 2018).

Santy Saptari, who was born and raised in Jakarta and now lives and works in Melbourne declared at the Mapping Melbourne exhibition, "Traditional lives are very orchestrated in Indonesia. ... Many women sacrifice their art for family commitments, getting married and putting the male first..." Saptari (2018:1). As with many other culturally inherited values and ideals, the role of Indonesian women in family life is firmly implanted in the thoughts, behaviors, actions and conversations of present day Indonesians.

Despite the Indonesian constitution Undang-undang Dasar⁴ (UUD1945) stipulating the rights of all Indonesia citizens and residents as equal before the law, this predominantly Muslim country rigidly follows the Marriage Act of 1974 that is based on Islamic and other religious and cultural principles. The Marriage Act highly regulates the customs and social life of all citizens (Marpinjun and Ramsey, 2017). According to this Act the husband is obliged to protect his wife and provide every necessity of life while the wife is required to manage the affairs of the household. Legal challenges to this Act are refused; judges base most of their court decisions on religious interpretations (Putri, 2015). Indeed according to many Muslim men they are, or will be when married, the head of the household and will make all the decisions; their wives, if Indonesian, will know this is their role and be subservient to their husband (Nanda, 2018).

As these examples show, discrimination and violence against women are not new phenomena in Indonesia: What is new now is that legal mechanisms for reporting violence and for protecting and supporting women and children have been put into place.

² *Merdeka*: Freedom. Indonesian's celebration of freedom from 350+ years of oppression by the Dutch.

³ *kanca wingking*: Literally 'back home.'

⁴ *Undang-Undang Dasar (UUD)*: The Indonesian Constitution.

1.4. Indonesian Legal Mechanisms for Reporting Discrimination and Violence against Women and Children

The *Pusat Pelayanan Terpadu Pemberdayaan Perempuan dan Anak (P2TP2A)*⁵ is an integrated service center mandated to empower and protect women and children from various types of discrimination and acts of violence, including trafficking in persons. Decentralized centers of this organization were formed by local government or community-based organizations in each sub-district: the quality of these very much depends on the wealth or amount of resources available in the area (Cahyani, 2018). A P2TP2A Centre was established under the coordination of the *Kementerian Pemberdayaan Perempuan dan Perlindungan Anak (Kemen PPPA)*⁶ (Cahyani, 2018).

Three different services are provided by P2TP2A, *Pusat Krisis Terpadu (PKT)*⁷, *Pusat Pelayanan Terpadu (PPT)*⁸, *Pusat Informasi Ilmu Pengetahuan dan Teknologi (PIPTEK)*⁹. PKT includes referral centers, business consulting centers, reproductive health consultation centers, legal consultation centers and integrated crisis centers. PPT provides integrated service centers, trauma recovery centers, women's crisis management centers, training centers, safe houses and shelter houses, while PIPTEK provides information centers on science and technology (Kemen, PPPA).

The increased reporting of violence by women may be attributed to the publicity drawn by the worldwide reporting and acceptance of the Me-Too movement. This movement has helped many women feel free to publicly share their traumas associated with discrimination and violence perpetrated against them by men (Me Too, 2018). Previously domestic violence in Indonesia was hidden and not discussed outside of the family and frequently only between the perpetrator and the victim, it was kept hidden by wife and husband (Cahyani, 2018).

2. BULLYING

In this paper bullying always entails an imbalance of power between the perpetrator and the victim. The perpetrator is usually stronger or more powerful in some way than the victim and uses her/his strength and power to intimidate the victim in one or more of the following areas on a regular basis (stopbullying.gov). Intimidation may occur Physically; by hitting, punching, shoving, pinching, taking money or belongings: Psychologically; insulting, threatening, depriving of food or love: or Emotionally; isolating, ignoring, name-calling or swearing at the victim (Shore & Cahyani, 2014).

The worldwide reported increase in bullying with the resulting deterioration of achievements in school, has recently gained even higher prominence both in the press and through social media channels, of children as young as 9 years of age who are committing suicide because of all types of bullying: This is a matter of major concern to all parents and

teachers concerned with children's growth and development (van Geel, Vedder & Tanilon, 2014).

Cyber bullying, a recent destructive bullying phenomena, has also had many deleterious effects on children. Initially the negative effects were on teenagers, however with the growing use of mobile phones by young students, it is now a serious problem with pre-teens. In Australian cyberbullying studies found girls were generally more likely to be victims reflecting the nature of their peer relationships (AISNT, 2019). This paper does not address cyber-bullying at SMS as the focus is on live bullying, person-to-person or people in groups.

2.1. Effects of Bullying Children in Schools

The damage that bullying and school-based violence does to the child and the learning process was first studied by Dr. Dan Olweus, a Norwegian research professor of psychology, often considered the 'pioneer' in bullying research and who published the first in-depth study of bullying in 1973 (Olweus, 1993). Dr. Olweus has long been a proponent of school safety as a fundamental human right. As early as 1981, he proposed enacting a law in Norway against bullying in schools to spare students the repeated humiliation implied in bullying. In 1983, subsequent to the research, the Ministry of Education in Norway, prompted by the suicide of 3 adolescent boys, initiated a campaign against bullying in schools. By the mid-1990s, these arguments led to legislation against bullying in schools by the Swedish and Norwegian parliaments (Roland & Munther, 1997).

Humiliation, taunting, threats and social ostracism by classmates are common school experiences for many children throughout the world with anywhere from 40% to 80% of students reporting they personally have been targets of bullies at school (Juvonen & Graham, Eds, 2001). While that research collection on bullying in schools is eighteen (18) years old, bullying is still as prevalent in schools as it was when their book was published.

2.2. Growth of Gender Equity and Anti-Bullying Awareness and Research

Awareness of bullying in schools and its associated detrimental effects on children's development has grown worldwide with many countries adopting an Anti-Bullying stance. Government programs such as the USA campaign by President Obama and his wife Michelle to Stop Bullying commenced in 2011 (the White House, 2011). Melanie Trump's BE BEST program in 2018 (Trump, 2018) followed the USA initiative while the Anti-Bullying Week in Great Britain (Bellis, A. 2018), and *Safe Schools* in Australia (Safe Schools, 2018) alerted nationwide awareness in those countries while promoting the importance of introducing Anti-Bullying programs in schools. The Indonesian Government Education Department, although a signatory to the *Konvensi Hak-hak Anak (KHA, 1989)*¹⁰ that guarantees children's rights to an education, and to feel safe in their learning environment, has not yet developed a national policy on Bullying in Schools.

A longitudinal study, by Ladd, Ettekal, and Kochenderfer-Ladd (2017) identified the effects of bullying on children's physical, psychological or emotional development and

¹⁰ *Konvensi Hak-hak Anak (KHA) 1989*: Convention on the Rights of the Child.

consequently how bullying affects a child's academic achievements. This study tracked three hundred and eighty-three (383) students from K–Year 12 finding that children who are bullied possess greater dislike of school, less confidence in their academic abilities and lower achievements than their peers who have not been bullied. In general though, gender differences in prevalence tended not to be statistically robust (Ladd, Ettekal, and Kochenderfer-Ladd (2017).

Lembaga Studi Perkembangan Perempuan dan Anak (LSPPA) an Indonesian feminist NGO in Yogyakarta has been advocating for the empowerment of women and children through education and training since 1991. LSPPA believes the only way to counter the embedded, male dominated belief in their superiority is to provide training in Gender Equity Principles, and Early Childhood Education to mothers with new babies (LSPPA, 2001). As an Australian volunteer, specializing in early childhood gender-equity education, the first author of this Chapter worked with LSPPA for 3 years (2001-2004) establishing the first Early Childhood Education Centre in Yogyakarta. Dr Shore voluntarily wrote the first Early Childhood Education Training curriculum for LSPPA in 2003 (Shore, 2004). NGO's receive no government funding or assistance to spread their messages or conduct training and LSPPA is reliant on other NGO's, overseas sponsors or volunteers for the continuation of their work.

With 4 Indonesian colleagues in 2004-2005, Dr. Shore was instrumental in the founding of SMS, a non-government inclusive school that, at that time, provided education solely for preschool age children. The curriculum stressed educating children with extra needs and promoting gender equity, thus ensuring that SMS was inclusive with children who needed extra learning assistance, and children of all genders having equal rights to all the facilities, equipment and resources available in the school. The Anti-Bullying program was introduced in 2006 to ensure children who were different from the mainstream population did not experience bullying.

From 2008 onwards the authors have presented research from SMS on the development of the Anti-Bullying program in a fully integrated school to promote awareness of how children with extra educational needs may be educated successfully in mainstream classes.

Plan International Indonesia (2015) stated that 84% of Indonesian school children had experienced bullying and in 2017 Bakar (2017) highlighted the problem that bullying behaviors in Indonesian schools remained critical and complex (Bakar, 2017). Handayani (2018), in an article in the South China Morning Post, quoted Sejiwa, an Anti-Bullying organisation in Jakarta, as saying that Java's main cities of Jakarta, Yogyakarta and Surabaya are seeing an alarmingly high rate of bullying of high school students (Handayani, 2018).

Between the years 2012 and 2017 the University of Gadjah Mada in Yogyakarta conducted 27 surveys and research programs examining the prevalence of bullying, and designing programs for the development of Child Friendly Classrooms where children learn in a climate free from fear of being bullied. These programs were conducted in 5 Yogyakarta kindergartens, 6 primary schools, 5 junior and 10 senior high schools, and 1 university. The surveys and research programs validated the original findings that bullying was prevalent in Yogyakarta kindergartens and high schools and endorsed many of the Anti-Bullying programs and activities that Sekolahku-MySchool had been using in pre-schools for more than 6 years, at that time (Kumara & Shore, 2018).

2.3. Anti-Bullying Training Programs for Teachers

The Indonesian *Komnas Perempuan*¹¹ commissioner Indraswari believes that the lack of quality gender education in Indonesian public schools is in part to blame for the rise in attacks against women (Indraswari, 2017). Apart from the reported rise in violence against women, children's experiences of bullying in schools are becoming well-known throughout education circles, mainly due to the work performed by Indonesian NGO's.

Olweus (1993) stated that knowledge about bullying among teachers is still not enough and teachers do not have the skills needed to deal with bullying. He developed the first Primary school prevention program in 1993, Olweus Bullying Prevention Program, Violence Prevention Works, first published in 2016. Statistics from this initial program were drawn from two thousand, five hundred (2,500) students in forty-two (42) Norwegian schools. These figures showed reductions of more than 50% in student reports of bullying, marked reductions of reports in general anti-social behavior and clear improvements in the classroom climate (Violence Prevention Works, 2016).

A shortened version of the SMS Anti-Bullying program in Kindergartens and a program adapted from the Olweus (1993) Anti-Bullying program was implemented and researched by Professor Kumara, the head of the Psychology Department at the University of Gadjah Mada (UGM) in Yogyakarta, from 2010 to 2017. Dr Kumara worked with cohorts of mixed-sex undergraduate and graduate psychology students who conducted a series of longitudinal studies in Yogyakarta Kindergartens and High Schools with teachers presenting their program and measuring the effects on young children and youths. Results of the above studies, that can be found in the book *Impeding Bullying in Young Children in International Contexts* published last year by Springer (2018), showed positive improvements in the classroom climate and the competence of teachers in building safe and comfortable classrooms. Furthermore, children's aggressiveness was reduced and their prosocial behavior increased (Kumara & Shore, in Hinitz, (Ed), 2018:100).

YTCG developed their training unit, UP3¹², in 2015 to organize observation and training visits of their Anti-Bullying and Teasing Program for groups of teachers from public and private schools throughout Indonesia. These groups observe the indoor and outdoor teaching and learning areas where students experience the bias-free, zero tolerance of bullying climate and activities. This whole school, total learning environment approach (Eslea & Smith, 1998; Slee, 2007) assists all children, and particularly the less fortunate, less skilled or less able students, gain the essential self-help or academic skills they require, depending on their developmental level. SMS trainers then offer the observers a short talk on the program's theoretical base before a Question and Answer session on the activities the visitors have observed. Herein the trainers provide information, clarifying the processes the visiting teachers have observed, and, where applicable, provide after-visit on-line assistance if required (Cahyani, 2018).

Recently fifteen (15) Javanese schools have selected UP3 for training one hundred and thirty-two (132) of their teachers during 2017 and 2018 in the SMS Anti-Bullying program. This program has been piloted, implemented and researched for over twelve years (Cahyani, 2018).

¹¹ *Komnas Perempuan*: National Commissioner for Anti-Violence against Women.

¹² UP3: *Unit Perkembangan, Pelatihan dan Penelitian*; Development, Training and Research Unit.

At the time of writing, individual Indonesian schools determine their own policies, programs and training on Awareness and Prevention of Bullying.

2.4. Who are the Bullies, Who are the Victims and Who is a Bystanders?

2.4.1. Bullies

Children who are bullies have been found to become bullies as they grow older. As adults, they may adopt a powerful and controlling attitude to those weaker or less powerful than themselves (Ttofi, Farrington & Losel, 2012). According to their roles this may be enacted in schools, in the workplace, in their social lives or at home with their families. Characteristics of bullies include low levels of moral reasoning and high levels of egocentric reasoning, they believe that aggression is an acceptable way to achieve their own goal. Bullies also show, among other characteristics, more emotional instability, they have a lower level of empathy than other students, possess poor impulse control and poor anger management skills (Victoria State Government, 2018).

2.4.2. Victims

Children who are different from the mainstream group of children are more likely to be bullied than those children belonging to the mainstream group. UNGEI¹³ (2017) describes children who are at greater risk of school violence and bullying are those with a disability, their gender (females), poverty or social status, ethnic, linguistic or cultural differences, physical appearances and sexual orientation, gender identity and expression (UNGEI, 2017).

According to MIND-MATTERS, SPOTLIGHT, (2019), an Australian Government mental health initiative, victims are children who lack quality friendships with peers and teachers, have low self-esteem, are relatively non-assertive, lack confidence and skills in interacting with peers, are less likely to have defenders when they are bullied, and are different in some way (MIND-MATTERS, SPOTLIGHT, 2019).

2.4.3. Bystanders and Upstanders

A Bystander is a witness who sees someone being bullied. Bystanders may be a friend, other student, teachers or school staff, parents or coaches. Being a supportive Bystander can occasionally be tough. Sometimes it is not easy to work out how to help safely because bullying happens in different ways and places such as on-line, at work or school (Australian Human Rights Commission, 2011). Instead of just watching a person become a victim of a bully, the Bystander could become an Upstander and take action to prevent the bullying continuing. Taking effective action could be as simple as changing the subject, diverting the behavior, using humor or just walking away with the potential victim (MIND-MATTERS SPOTLIGHT, 2019).

3. THE CONTEXT OF THE STUDY

SMS is an inclusive school that values diversity in all its forms. It was founded as a Playgroup in 2004-2005 by an Australian volunteer and 4 Javanese nationals to fill the

¹³ *UNEGI*: United Nations Girls' Education Initiative.

educational needs of various groups of Indonesian children denied access to the governmental education system. Children whose *Akte Kelahiran* (Birth Certificate) did not list the father, or those children suffering from psychological, physical or emotional developmental disturbances were denied access to mainstream government schools. A few government schools catered for a few children with specific physical development problems and a few children diagnosed as being on the autism spectrum were accommodated either in schools run by non-government organizations (NGO), or by private endowments that could be philanthropical or profit-making machines. SMS is a not-for-profit organization (NPO) with funding provided by parental fees that also assist with scholarships for the not so fortunate child.

Of the initial 5 children, who commenced with SMS, 3 owned extra needs requiring specialized assistance. These 5 children were quickly joined by more non-mainstream students whose parents were experiencing difficulties with the rigid rules and requirements of the former and present Governmental school regulations. As news of the quality of the early childhood education at SMS spread throughout Yogyakarta, mainstream parents, particularly those from other countries or areas of Indonesia outside Java, decided to enroll their young children at SMS. Within two years the enrolments had grown to over 50 children and in the fourth year SMS moved to new premises to accommodate the growing numbers of pre-school children. At the same time, in response to parental request, Elementary School Year 1 opened with an initial 12 children.

These early numbers have now swelled to two hundred and eighteen (218) children in classes from Playgroup to Elementary School level, Year 6. Girls make up 39% of the school population (Figure 1). The initial diversity of children still persists with 10% of children having experienced difficult physical, psychological or social discrimination that requires additional assistance, and up to forty (40), or 20% of all children, originating from non-traditional Javanese cultural, or ethnic backgrounds.

Since the writers of this Chapter introduced the word and concept of 'Bullying' into general usage in Java, Indonesia in 2005, acknowledgement and identification of the impact of bullying on children's development has become common parlance in educational circles throughout Indonesia. SMS has implemented a whole school approach through a Gender Equity program followed by an Anti-Bullying program that seeks to ensure girls have equal opportunities with boys to experience quality early education without fear. The Gender Equity program has now operated for 15 years and the Anti-Bullying program for 12 years with the Play Group and Kindergarten classes and 10 years with the Elementary classes.

3.1. Introducing a Gender Equity Program in Sekolahku-MySchool

The Gender Equity policy written and mandated in the original Vision and Mission statement of SMS, 2004-2005, still holds a dominant place in the updated school documents of Yayasan Tunas Cerdas Gempita (YTCG, 2017)¹⁴. All resources, toys, and games have been selected for their unisex properties. Indonesian children's unisex books were however, as were books on Bullying, very difficult to source in 2005. A selection of gender inclusive and Anti-Bullying books were imported from the USA, translated and interpreted by SMS staff, who adapted the content for language and cultural differences (Shore, 2018).

¹⁴ YTCG: governing body of Sekolahku-MySchool and Unit Perkembangan Pelatihan dan Penelitian.

Teacher training at SMS in implementing gender equity policies and practices in the classrooms has occurred spasmodically over the past fifteen (15) years as gender awareness is written into the SMS curriculum and all the recommended activities. However as Marpinjun and Ramsey (2017) found in their Gender Equity Workshops, values that have been passed down and embedded in families over many centuries still persist in reality, even when indisputable evidence and the participants' own intellectual knowledge, acknowledges such cultural practices are no longer valid.

Examples of the continuing favoring or responding to male students, and ignoring of females' qualities in classrooms, has been witnessed recently at SMS by the first writer. An employee of 10 years, in charge of an elementary class at SMS selected 5 boys to be on a debating team even though the girls were more knowledgeable and had better arguments. The girls were quietly persuasive whereas the boys were demanding and loud, often repeating the same texts frequently as they had not, unlike the girls, studied the subject deeply (Shore, 2018). Two other examples occurred with the same teacher selecting boys to help rearrange classroom furniture, and another team of boys to organize the library. When this was pointed out the teacher's only reasons were "I forgot" and "The boys were nearest." These are clear examples of using embedded values to make inherently biased decisions and not using intellectual knowledge to ensure SMS Gender Equity policies are enacted (Shore, 2018a). Parents however have attributed the school's growth in physical size and numbers of children now attending to its reputation as a school that enacts Gender Equitable principles for girls and an Anti-Bullying program that contributes to the positive climate of the whole school: These accolades indicate some successes with the two policies (YTCG, 2018).

3.2. Introducing an Anti-Bullying Program in Sekolahku-MySchool

As the original cohort of students at SMS grew larger and more diverse it became obvious that bullying could easily occur between such a diverse group of children. The School Board, comprising 52% Indonesian nationals, decided to introduce the concept and activities of an Anti-Bullying program, The Anti-Bullying and Teasing Program for Kindergartens (Sprung, Froeschel & Hinitiz, 2005) to be imported from the United States of America (USA) to counteract any possible bullying. The program was submitted to the Parent Committee for their approval in 2006 (Sekolahku-MySchool, 2006). Bullying at that time was a new concept as the general belief in Indonesia was that violence towards and between children was quite a normal happening and part of 'growing up' (Head of School Report, 2006). Punishment, sometimes quite violent, could be meted out by parents, community elders or school teachers as part of the socialization process. In remote parts of Indonesia it was common to see parents whipping their child with a *sapu lidi*¹⁵ to make them go to school (Shore, 2006). In 2015 in Kupang, Nusa Tenggara Timur (NTT), Indonesia school teachers were still seen to punish students in front of the whole school for not knowing the answers to the teacher's questions (Hartig, 2015).

The Board of SMS had procured the Anti-Bullying and Teasing year-long program (Sprung, Froeschel & Hinitiz, 2005) and the supporting resources from the USA in 2006. The program had been written and trialed previously in the USA and the Board sought parental permission to introduce it school-wide into the yearly curriculum at SMS, at the same time

¹⁵ Sapu lidi: broomstick.

requesting their support in the home. With some hesitation and the Board's reassurance to allay parental fears of having other values imposed on their children, parental approval was finally given and the program commenced late in 2006 (YTCG, 2017. Shore, 2018b).

Since that time parents have been an integral part of the SMS Anti-Bullying program attending discussions and information giving by SMS senior staff on new strategies or activities that have been incorporated into the weekly activities. Parents now confidently discuss any bullying behavior they hear of, or see, with staff and, when reported to school leaders and management, it is usually addressed immediately by one of the consultants (Cahyani, 2018). The SMS Open-Door policy has supported this translated and culturally adapted program to be extensively observed and researched by SMS staff, Undergraduate and Post-Graduate University students, practicing school teachers and other parties interested in this uniquely SMS program (Shore, 2018a). Parental satisfaction and communication channels in Indonesia have contributed to the growing number and diversity of students now attending the school.

In successive years since its inception, the Anti-Bullying program has produced extensive benefits, developing a positive school climate and providing a safe and secure learning environment for challenging programs to children with a myriad of learning problems (Shore, 2018b). This fully researched and proven program has assisted tens of children on the autistic spectrum, children who have been bullied in previous environments, and others with a variety of physical, social and emotional impediments to learning, successfully graduate from Primary School with many happily and successfully integrated into mainstream higher-level schooling (Shore, 2018b). This ongoing research program has been presented nationally by the authors and staff at conferences throughout Indonesia, and internationally in Australia, Hong Kong, Sweden and the USA: It has been recorded in a published magazine article (Wibowo, 2010) and in 2 chapters of a recently published book (Hinitz, B., Ed. 2018).

4. METHODOLOGY

4.1. Data Gathering

4.1.1. Permission: Children

All thirty-three (33) parents gave written permission for their girls (App.1) to be interviewed. Girls surveyed ranged in age from 6.7 to 12 years of age attending Elementary classes in Years 2- 6 (App.4).

4.1.2. Child's Personal Data

Data regarding the girls' ages and classes were accessed from children's enrollment forms and class teachers, and verified by the Heads of School and the first and second writer of this chapter.

4.1.3. Interviews with Girls

Individual interviews of the thirty-three (33) girls were conducted and recorded by the education consultant, the Head of School and their class teachers. Questions covered when they commenced at SMS, whether they broke the classroom rules and how they felt if they did break the rules: their present knowledge of bullying; if they had been bullied, or seen bullying

occurring at SMS or at their previous school; and what if anything, they did about bullying they had seen as a bystander (App. 4 & 5).

4.1.4. Child Questionnaire

8 questions were selected for relevance to Bullying behavior (App. 4). The selection of questions was based on the authors' combined 40 years of studying the theories and research of bullying and classroom practice, the writers attending seminars, training and workshops, and hands-on teaching in Kindergarten and Elementary classrooms. The first writer has more than forty (40) years' experience, and the second writer has ten (10) years. The questions are based on:

- 1) Early school experiences
- 2) Play preferences
- 3) Keeping Classroom Rules
- 4) Feelings after breaking rules
- 5) Understanding of bullying
- 6) Experience of bullying

All girls experience of bullying was divided into:

Q7) Group 1, girls who attended SMS Play Group or Kindergarten before elementary levels

Q8) Group 2, girls who transferred into SMS at Elementary levels

4.1.5. Interviews: Teacher and Head of School

One teacher was interviewed to clarify the report of a girl being bullied, the incident that prompted this research. While teachers may provide an insight into the problem, sometimes they may be the cause of, or exacerbate, the child's behavior. This maybe because they have no strategies or tactics to address the behavior, they just don't realize the effect bullying can have on the child, or they think it better not to intervene and the behavior will go away by itself. The Head of School, who was also interviewed, must be aware of all happenings, positive and negative to all children during the Early Childhood years, and intervene if the teacher is not coping with the class. In this paper SMS early childhood stretches from 16 months to 12 years, the completion of the elementary years of schooling. At SMS the teachers take the role of '*loco parentis*', adopting the role of the carer as well as the educator of the child (Shore, 2018a).

5. CODING AND ANALYSES

The thirty-three (33 girls) were divided into 2 groups: Group 1 - the girls who had experienced the Anti-Bullying program at SMS Play Group or Kindergarten: Group 2 - the girls who transferred into SMS at elementary level.

Simple counting, visual comparisons, percentages and classroom observations by the consultants were used in this exploratory research to provide an indication of the possible areas for future in-depth research and analysis.

Figure 1. Group 1 and Group 2 commencing Elementary experience.

5.1. Q1: Early School Experiences: Anti-Bullying Program

Group 1 joined SMS during the Pre-Elementary years; Group 2 commenced SMS Elementary immediately from home or another school.

Group 1 (G1), 42%, had experienced the Anti-Bullying program in Play Group or Kindergarten). No other known schools in Yogyakarta have a dedicated Anti-bullying program for pre-elementary children. Group 2 (G2), 58% had no previous experience of Anti-Bullying programs (Figure 1).

5.2. Q2: Style of Play

Children who like solitary play are more likely to be the victims of a bully than those who play cooperatively (Gordon, S. 2018).

Of Group 1, no child preferred solitary play, in G2 12% preferred to play alone (Figure 2).

Figure 2. Girls Solitary or Cooperative Play.

5.3. Q3: Breaking the Rules

Classroom Rules are made collaboratively between teachers and children at SMS. Learning these rules and keeping them are the foundation of a positive classroom climate (Shore, 2018).

Less girls in Group 1 (36%) than in Group 2 (49%) broke the classroom rules (Figure 3).

Figure 3. Keeping and Breaking Classroom Rules.

5.4. Q4: Feelings after Breaking Rules

The input of information and activities, the child's feelings about breaking rules and internalizing the messages of the Anti-Bullying activities until they are below the level of consciousness, will determine whether the behaviour will be repeated or not.

Figure 4. Group 1 and Group 2 Feelings After Breaking Classroom Rules.

Almost the same percentage of all girls, Group 1, 28%, and Group 2, 27% of all girls admitted they had negative feelings after breaking the classroom rules. 12% of both Group 1 and Group 2 girls were not concerned if they broke the rules (Figure 4).

5.5. Q5: Bullying Behavior

Every week each class has specific Anti-Bullying activities that introduce and reinforce children’s understanding of behavior that constitutes bullying.

Figure 5. Group 1 and Group 2: Understanding Bullying Behaviour.

All girls at SMS are familiar with the term Bullying and understand the factors that constitute bullying behavior (Figure 5).

5.6. Q6: Experience of Bullying

It is expected that Group 1 will have experienced the Anti-Bullying activities in SMS Pre-Elementary classes: Group 2 will not have experienced Anti-Bullying activities in their previous schools.

Figure 6. Bullying Experiences: Group 1 and Group 2.

Of the 33 girls interviewed, 33% had experienced bullying, 52% had been a bystander (Figure 6)

5.7. Q7: Bullying Experiences: Group 1

It is expected that Group 1 will have experienced less bullying behavior than Group 2.

Figure 7. Bullying Experiences: Group 1.

Of Group 1, 31% had been bullied, 54% had been Bystanders, only 15% had no experience of bullying (Figure 7).

5.8. Q8: Bullying Experiences: Group 2

It is expected the Group 2 will have experienced bullying incidents at their previous schools

Figure 8. Bullying Experiences: Group 2.

Of Group 2, 35% had been bullied and 50% had been bystanders (Figure 8).

The results of the questionnaire from this exploratory study follow. The results are enriched with comments from some of the girls.

6. RESULTS AND DISCUSSION

6.1. Q1: Early School Experiences

Results from the 33 girls interviewed at SMS showed that Group 1, 42%, had experienced an Anti-Bullying Program at Kindergarten before entering Elementary School; Group 2 at 58% possibly had more exposure to bullying (Figure 1).

6.1.1. *Girls' Comments*

Group 1 girls G124, G135 G113 commenced at SMS because their parents were told 'SMS is an Anti-Bullying school'. G113 'used to bully other children' and G135 exclaimed 'friends are very friendly'.

In Group 2, G613 mentioned the reasons for choosing SMS were 'she needed daycare', and G518 felt 'in my old school was too much homework and burdensome for children'.

6.2. Q2: Style of Play

All Group 1, 42%, preferred to play with friends while 12% of Group 2 said they would rather play alone (Figure 2).

6.2.1. *Girls' Comments*

Group 1 girls all preferred to play with friends saying it was 'more fun' and 'not boring with friends'.

Group 2 girls who preferred solitary play recorded they liked 'being calm' (G226), 'didn't like being disturbed' and 'other girls don't follow the game instructions' (G215), because 'friends cause problems' (G15).

6.3. Q3: Keeping Classroom Rules

A large percentage of all Group 1, 36%, and Group 2, 49%, girls admitted to breaking the classroom rules (Figure 3).

6.3.1. *Girls' Comments*

Group 1 girls breaking rules included 'talking in class' (G113), 'damaging goods' (G133), 'disturbing friends' (G118), and 'running' in walking only areas, (G159).

Group 2 breaking rules included 'interrupting other people's conversations' (G414).

6.4. Q4: Breaking Classroom Rules: Feelings

Group 1 had 28% and Group 2 had 27%, negative feelings after breaking the classroom rules (Figure 4).

6.4.1. Girls' Comments

Group 1 girls commented that they felt 'guilty' (G414, G132), and 'uncomfortable' (G131, G132, G414, G436) when they broke the rules. Others felt 'bad' if they were found out (G432, G531).

Group 2 girls told of feelings of 'guilt' and 'shame' (G231, G456, G333), being 'very uncomfortable' (G433, G456), experiencing 'sorrow' and 'sadness' (G331), and G235 felt 'weird and uncomfortable' about breaking the classroom rules. Feelings of 'not being worried' were voiced by (G132).

6.5. Q5: Understanding the Constitution of Bullying Behavior

All participants in this study (100%) were able to describe accurately what constitutes Bullying (Figure 5).

6.5.1. Girls' Comments

In Group 1 G524 and G534 showed their knowledge of bullying and G524 shared her experience of 'being bullied in Australia'; G534 noted her information came from 'books and the internet'.

From Group 2 G675 said she knew about bullying from her mother while G335, G336, G547, G548, G549, G613 received information from SMS.

6.6. Q6: Bullying Experience: Groups 1 and 2

At 33% the bullying experience of **Group 1** and **Group 2** girls combined is lower than the national average lowest score found of 40%: the 52% of girls who acted as Bystanders to bullying incidents presents a challenge (Figure 6).

6.6.1. Girls' Comments

G545 in Group 1 recalled 'In my kindergarten before there were many bullies. Boys were hostile to girls, my friends were pushed to the ground, and the teacher really didn't care.' G457 related how, living in another island 'I was often mock(ed)', G723 told of seeing 'usually the most bullied in SMS is special child'. She is 'usually teased and told to bully others... would say yes if told anything, for me it was bully too because they told her to bully friends' One girl, G654 stated 'there is no bullying here, they only joke too far which causes problems'.

From Group 2 G46 commented that she had heard 'boys who mocked each other's tribe (culture)' and G633's 'name was often mocked by boys'. G613 said 'my neighbor often bullied me, ...said I am ugly', and spread 'gossip' about me'. Other girls were 'pinched' (G654) and 'pushed' (G51) by boys.

6.7. Q7: Bullying Experiences: Group 1

In Group 1, 31% had been bullied while 54% became Bystanders or Upstanders to bullying (Figure 7).

6.7.1. Girls' Comments

Four Group 1 girls G366 G461 G654, G765, were Upstanders telling the bullies 'to stop' while 3 more girls G162, G263, G366 'report(ed) the bullying to the teacher'.

6.8. Q8: Bullying Experiences: Group 2

There is little difference between Group 1's experiences of being bullied at 31% (Figure 7), and Group 2's bullying experiences of 35% (Figure 8); the experiences as a Bystander in Group 1 at 54% (Figure 7), and in Group 2 at 50% are also very similar (Figure 8).

6.8.1 Girls' Comments

In Group 2 G723 continued 'I told her (victim) don't follow them.' and, being an upstander 'I immediately said to the perpetrator that it can't be like that', he just said 'Whatever'... G734 said 'Stop. ...everyone is different – no need to bully'..., however G755 commented 'I want to warn (him) but I'm afraid ...I report to the teacher'. Other girls confronted the bully G777, G778, G779 telling them to 'STOP', while G485 and G713 remained silent because they were afraid of the bully's retaliation.

7. CASE STUDY: G226

Date: November 9, 2018 at Sekolahku-MySchool (all interviews were conducted in Bahasa Indonesian and some editing has been done for clarity).

7.1. Personal Profile of G226

G226 is 11 years old and was born, raised and schooled until 8 years of age in Medan in Sumatra, Indonesia. Her mother is Indonesian and her father is Dutch. The family moved to Java for personal reasons. The parents are professional people with full-time working lives and rarely visit the school. In many ways G226 is very different from other children in SMS. Physically she is taller, bigger and whiter than the other children, her hair is brown while all other children in the school have black hair.

G226 is extremely talented and speaks 2 languages, Indonesian and English, fluently. Culturally G226 was raised in an environment where communication is direct and to the point. This is quite the opposite to the Javanese person's manner whose generally accepted habit is to use different expressions in conveying a purpose. For example, a mother does not need to tell her child that she is angry. Simply by being silent for some time and not responding to her child, then the child is expected to know that the mother is angry.

Another distinguishing factor about G226 that is different from the other children is the educational model developed by her family which keeps her free from very little adult direction. This situation appeared to have contributed to hindering G226's adjustment to her new environment when she moved to a different island with a new school, new teachers and new friends with different cultures and habits.

7.2. Consultant Interview with G226

7.2.1 Joined SMS

Q: Since what grade did you join this school?

G226: Grade 4

Q: Do you feel comfortable here?

G226: mmm, ... yes

Q: You sound not really sure

G226: Yeah. Boys bully me sometimes

7.2.2. Style of Play

Q: Which one do you prefer, alone or playing with your friends?

G226: I like playing by myself. I enjoy playing alone. I am the only kid of my parents. And every time I played with my friend, there would be a problem.

7.2.3. Bullying Understanding

Q: Ok, tell me what bullying means for you?

G226: Bullying means like you saying nickname to your friend, or you hurt your friend or tease them.

7.2.4. Bullying Victim

Q: What do boys do to you?

G226: I was playing puzzle today, teacher ask me to tidy up, but I was not finish yet, so teacher give me 5 more minute(s). Then in a while F came to me and ruined my puzzle. I was working very hard on that puzzle and it was almost finished.

Q: Why do you think he did that?

G226: He wants me to pack away the puzzle, but the teacher already gave me 5 more minutes to finish it. He did not believe me, and just knocked the puzzle down.

Q: What did you say to him then?

G226: I did not say anything. I just almost cry.

Q: Did you tell your teacher about it?

G226: No, I am afraid F would blame me for what I said

Q: Has it happened a lot?

G226: Sometimes. Sometimes I fight back. F ever punches me

Q: What??? Why do you think he did that?

G226: He started it. He called me 'paus' (a whale). And I got mad, I shouted at him to stop

Q: Do you always show angry reaction when he teases you?

G226: yes

Q: Like always ... always ... all the time?

G226: Yes. I asked him to stop

Q: What was his reaction back then?

G226: He said I have too many excuses

Q: Explain to me that part, what did he mean by that, you have too many excuses?

G226: I don't know. I just ask him to stop.

7.3. How the Teacher Handles the Situation (Consultant Report)

It must be admitted, that all the differences that exist in G226 caused bias to the teacher's handling of the situation. The way G226 responds to the teacher and her friends raises the stigma that G226 is a difficult child. G226 is easily offended and it is difficult for her to accept input from other people. This attitude reinforces the teacher's belief that it is natural for G226 to have a lot of problems and is rejected when socializing.

What the teacher didn't notice was the fact that G226's difficult behaviour was caused by the absence of her diplomacy skills. The negative reactions from friends stemmed from their failure to respond appropriately to situations they had never faced before.

Every time the teacher finds a difficult situation with G226, she just tries to persuade her without trying to map the problem and help G226 reflect. Also, the lecture method used to persuade the girl is clearly not an effective method for this situation.

Significant changes only occurred when the point-giving system for good behaviour was applied in G226's class. She is motivated to get many points because the holder of the most points has the opportunity to determine the game, book or activity that will be carried out in class.

This method appears to be successful because it helps children practice their new skills by receiving the right social response in the form of consequences and rewards (Cahyani, 2018).

7.4. Interview: Elementary Teacher

An Elementary teacher was interviewed to provide her perspective of this bullying incident as the bullying had persisted for over a year without the Consultant or Management being aware. It was brought to their attention when a parent complained that her daughter was being bullied by BF and became a bully herself. The teacher's report, following, is of her interpretation of G226's conduct and description of her response to BF and the situation.

7.4.1. *Bullying Situation: Report by Teacher 1*

G226 is always bitchy and fierce when answering questions. BF is upset with G226's bitchy behavior and calls her 'whale'. G226 gets upset when BF called her 'whale' then G226 writes on the blackboard that BF is crazy. G226 and BF become angry and shout at each other. BF pushes G226's shoulder in annoyance. G226 cries and reports it to the teacher.

The consultant followed up this report in an interview with the Head of the Elementary School.

7.4.2. *Date: November 9, 2018. Consultant report to YTCG about a Bullying Complaint at Elementary School*

Year 5-6 is a combined class of twenty-two (22) children with eleven (11) girls. G226 and BF were new to the school in Years 4 and 5 respectively. The Head of School (HOS) reported that G226 is more mature and advanced than her other friends and is not interested in joining class learning activities. She often rejects the teacher's instructions, does not do assignments and openly carries out different activities such as drawing during other lessons.

BF felt that the teacher allowed G226's defiance because there were never any consequences for her refusal to join activities. Conversely BF felt that his efforts to obey the

teacher and keep the class rules did not give him any advantage, making him feel that the teacher was acting unfairly.

The consultant explains G226 used to do everything she wanted, no-one had ever explained the effect her defiance had on the group and BF had no ability to explain what he thinks and feels.

BF's dissatisfaction spilled out onto G226 every time he saw her defy the teacher and responded with violence. This violence could take the form of taking G226's drawing books, throwing away her pencil or other items of her possessions.

Each time a disturbance occurs between the two, G226 reports it to the teacher who then punishes BF by preventing him from joining 'Free Play' time. However, this was never strictly enforced.

This situation frustrated everyone. G226 felt she was a victim of bullying, BF was upset because he felt that he was being treated unfairly and the teacher was frustrated because the commotion between the two happened almost daily: the parents were not satisfied because they thought the report was ignored by the teacher, and the situation only improved after the parents complained to the Yayasan. The parents complained that their daughter was bullied and no solution had been offered from the school. The head of the Yayasan forwarded the report to the consultant who followed the situation up with recommendations of possible behavior management systems that might work in this situation.

This study may draw attention to how we can further improve the quality of the classroom climate at SMS, instill gender equity principles and practice in all teachers and staff, and increase the enjoyment of learning in all girls, and particularly those who have extra learning needs that teachers or other people may not understand. This case study illustrates that school leaders must know and be aware of the learning climate in each classroom, the ability of every teacher to show empathy and understanding of girls and those who are different, and how to assist boys respect and care for the girls and children who need extra assistance.

CONCLUSION

Many girls commenced at SMS because of the Anti-Bullying program, and the lack of pressure of doing homework.

It was not obvious in this study that girls who experienced the SMS Anti-Bullying program in Pre-Elementary classes experienced less bullying than those girls who commenced in Elementary School. It emerged however that many girls in both groups used the Anti-Bullying strategies taught in the AB program to hinder, stop or prevent the bullying taking place.

The majority of all the girls had broken the Classroom Rules with over half of them experiencing negative feelings afterwards. Shame, sorrow and guilt were among the most frequent feelings experienced by the girls after breaking the rules. This reinforced the Activity Theory that reminds teachers of the time needed, with repetitions if necessary, before information and instructions sink below the level of consciousness and become everyday operations.

All girls were able to describe accurately the constitution of bullying behavior. The findings confirmed previous research that revealed that the children most likely to be bullied

were those who are different from the mainstream group: the case study girl was physically and culturally different, exceptionally talented and preferred playing alone.

The Case Study revealed a serious problem with reporting procedures for bullying in SMS with a situation not known by management until a parent complained. Streamlined reporting of difficult cases from child to teacher to Head of School to School governance is essential.

A long-time teacher's response to the bullying situation with a child who was different from the mainstream, showed a complete lack of understanding of the difficulties for children in adapting to a new culture, new friends, new environment and new ways of doing things. More in-class supervision of underskilled teachers who are not empathetic in classrooms is urgently needed.

Discrimination and bullying are alive and well in SMS despite the emphasis on planning and activities to reduce or eliminate these major issues being written into SMS policies and plans. While parents comment on the welcoming climate in the school, frequent in-service training and workshops for teachers addressing Gender Equity, and a year-long, whole school Anti-Bullying program, little change in some teachers' cultural habits appear to have been generated. Discrimination against girls and blaming 'difficult' girls for classroom upheavals and bullying, involving boys also, is a reflection of the discrimination in the wider society.

The preliminary findings in this study indicate that, despite fifteen years of a Gender Awareness focus and influence to the programs in SMS, teachers still fall back on their culturally embedded habits of selecting males to perform physical tasks or make presentations in classrooms.

All girls' understanding of, and possible responses to, bullying were similar. The study found that of the Group 2 girls who transferred into SMS, those who were bullied was because of their differences, physical, intellectual or talented, and, it appears their preference for solitary play: one had been a bully previously and one became a bully in retaliation for being bullied. All girls interviewed in SMS Elementary school and witnessing bullying incidents, tended to use strategies from the Anti-Bullying program to prevent the bullying thus becoming Upstanders instead of Bystanders to bullies. These girls said STOP and used body language to show disapproval of the behavior. After three attempts to prevent the bully from continuing, they would report the bully and the behavior to the teacher or responsible adult.

A case study describes a talented girl G226 who was constantly bullied by a male perpetrator BF. Both had transferred into SMS and were in Grade 5. Cultural differences, lack of prevention strategies by the teacher, the girl's preference for solitary play, and her parents' mode of parenting appear to be the causes of the bullying.

This study confirms many previous findings about the cause and incidence of bullying in schools, and the partial success of the Anti-Bullying programs in SMS. No other known schools in Indonesia have a dedicated Anti-Bullying program at Play Group or Kindergarten levels that follows through into the Elementary school years. The study confirms the need for updated and dedicated year-long Gender and Anti-bullying programs to be introduced in all Early Childhood Centers and continued until the end of elementary school.

RECOMMENDATIONS

- initiate a comparative research program into the extent of bullying throughout SMS identifying the prior schooling history of all SMS children, and the incidence of:

- pre-elementary school bullying between girls and boys
- elementary school bullying between girls and boys
- boys bullying boys
- girls bullying girls
- write and deliver short age-relevant lessons to all children transferring into SMS informing them of the SMS Gender Equity and Anti-Bullying policies and program focus, its effect on the school climate, the purpose of the Classroom Rules, and the consequences for any bullying behavior
- write a training program for all SMS teachers that reinforces the Gender Equity and Anti-Bullying focus, its effect on the school climate, the purpose of the Classroom Rules, and the consequences for any bullying behavior. Include:
 - indicators of bullying in their classrooms
 - positive strategies and tactics to prevent and stop bullying occurring
- approach teacher-training institutions to include Anti-Bullying and Gender Equity principles and practice into their undergraduate and graduate teacher-training courses.

APPENDIX 1: PARENTAL PERMISSION FORMS (ENGLISH)

Dear Parent,

With this letter, we inform you that in the next few months, we will carry out data collection in the framework of the Anti-Bullying program research project in schools. This activity was carried out to help draft the Anti-Bullying program that is relevant for all children in an effort to create schools that are free of bullying. The results of this study will be published in one of the chapters in the book that will be written by Dr. Margaret Shore and Riana Cahyani S.Psi. This book will be published by Nova Publishing in the United States in 2019. To avoid identification, all names involved in this study will be changed and all publications regarding this research can only be done with the permission of Sekolahku-My School.

Please allow the parents / guardians to complete the form below, as a statement allowing or not allowing children to be involved in this research. We hope that this form can be returned to school as soon as possible. If there are questions or information that you need, you can contact us at the email address: margaretshoredr@gmail.com or callmeriana@gmail.com.

Sincerely,

Dr Margaret Shore

Riana Cahyani S.Psi

APPENDIX 2: PARENTAL PERMISSION FORM (INDONESIAN)

Dear Parents,

Bersama surat ini, kami beritahukan bahwa dalam beberapa bulan ke depan, kami akan melakukan pengambilan data dalam rangka penelitian program *Anti-Bullying* di sekolah. Kegiatan ini dilakukan untuk membantu penyusunan rancangan program *Anti-Bullying* yang relevan bagi semua anak sebagai upaya untuk menciptakan sekolah yang bebas *bullying*. Hasil Penelitian ini akan dipublikasikan dalam salah satu bab di buku yang akan ditulis oleh Dr Margaret Shore dan Riana Cahyani S.Psi. Buku ini akan diterbitkan oleh *Nova Publishing* di Amerika Serikat pada tahun 2019. Untuk menghindari Identifikasi, semua nama yang terlibat dalam penelitian ini akan diubah dan segala publikasi mengenai penelitian ini hanya bisa dilakukan atas ijin Sekolahku My School.

Mohon kiranya Bapak/Ibu wali murid melengkapi formulir di bawah ini, sebagai pernyataan mengizinkan atau tidak mengizinkan anak terlibat dalam penelitian ini. Kami mengharapkan sekali jika formulir ini dapat dikembalikan ke sekolah secepatnya. Jika ada pertanyaan atau informasi yang Bapak/Ibu perlukan, dapat menghubungi kami di alamat email: margaretshoredr@gmail.com atau callmeriana@gmail.com

Hormat Kami,

Dr Margaret Shore

Riana Cahyani S.Psi

Surat Ijin Orang Tua

Saya, _____ (nama orang tua) memberikan ijin anak saya yang bernama - _____ (nama anak) untuk terlibat dalam penelitian program *Anti-Bullying* di Sekolahku-Myschool, Yogyakarta.

APPENDIX 3: RATIONAL FOR BULLYING QUESTIONNAIRE TO ELEMENTARY SCHOOL STUDENTS

1. Early School Experiences

Early school experiences may incite children to develop positive or negative feelings towards learning. Making that experience enjoyable, exciting and challenging for the child will

contribute to the child's and parents' satisfaction. According to Kumara and Shore (2018) it is a positive school climate that assists children to enjoy learning (Kumara & Shore, 2018). The positive school climate is created, among other criteria, by committed teachers and other staff respecting each other and the children, and all having a common understanding of the school philosophy, and a mutual meaning structure of its vision and mission (Shore, 2000). Potential school parents quickly recognize this climate and that helps them make a choice if they are undecided.

2. Play Preferences

By elementary school most children have passed the solitary level of play development and would prefer to play co-operatively. Children who prefer to play alone may be, or prone to be, a victim of bullies.

3. Keeping Classroom Rules

Deciding collaboratively on Classroom Rules is an important part of the Anti-Bullying program at SMS. With rules that focus on respect for each other, helping and caring for their friends and not interrupting the learning, when introduced in Play Group or Kindergarten classes, become part of the total school environment.

4. Feelings After Breaking Rules

Girls who have the ability to recognize and act on the reasons for making classroom rules, have mastered the recommended actions that then sink below the level of consciousness and become part of their everyday operational functioning (Shore, 2000). Those girls who break the rules are still developing the intellectual ability to recognize and act on the reasons for having classroom rules.

5. Understanding the Constitution of Bullying Behaviour

Girls who are bullies or who know what bullying behaviour is, can try to stop it as a victim or bystander, if they are taught proven strategies; these could be using either words or actions.

6. Experience of Bullying

Social Media communication channels ensure that news about all types of face-to-face bullying, physical, psychological or social, and cyber bullying is now freely available around the world.

7. Bullying Experiences of Girls who Attended SMS Pre-Elementary Classes

Many reasons prevent girls from being actually involved in a bullying incident and become a Bystander. Bystanders could be scared of being hurt if they become involved; they might agree with the bully; they may think it is none of their business. With adequate strategies they could change this response by becoming an Upstander who takes action either with the victim, or against the predator, or, finally, report it to a senior person.

8. Bullying Experiences of Girls who Transferred into SMS Elementary Classes

The reasons parents transfer their child from one school to another after they have commenced elementary could be as varied as moving house, child going to live with a relative, a different curriculum or program, or convenience to a parent's workplace. Having no friends or being bullied at their previous school could also cause parents to change their child's school.

APPENDIX 4: QUESTIONNAIRE - CHILD (ENGLISH)

Questionnaire re: Cultural and Gender Differences in an Inclusive school in Java Indonesia

This questionnaire is part of a research project to ensure our Anti-Bullying program is relevant to each child. The research project chapter will be written by Dr Margaret Shore and Ibu Riana Cahyani and published by Nova Publishing in the USA next year. All names of participants will be changed to avoid identification. We trust you will assist us by answering the questions below that will help us develop a deeper awareness of the different cultural habits, mores, ways of thinking and gender development that improve our programs.

Personal Information:

Children (initial/Birth Date/Sex): _____ / _____ / _____

Length of time at SMS: _____

Research Questions:

1. Do you know all the rules in the classroom? Have you ever broken the rules? _____
2. How do you feel about breaking the rules? _____
3. Do you prefer to play alone or with friends? Why? _____
4. Do you know about bullying? What is it? How do you know about it? _____
5. Have you ever seen or experienced bullying? What did you do? _____

APPENDIX 5: Kuesioner - Child (Indonesian)

Kuesioner: Perbedaan Budaya dan Gender pada sekolah Inklusif di Jawa Indonesia

Kuisisioner ini adalah bagian dari proyek penelitian guna memastikan program Anti-Bullying kami relevan untuk setiap anak. Penelitian akan ditulis oleh Dr Margaret Shore dan Riana Cahyani untuk diterbitkan oleh Nova Publishing di Amerika Serikat tahun depan. Semua nama subyek penelitian akan diubah untuk menghindari identifikasi. Dengan menjawab kuisisioner ini, bapak dan ibu telah membantu kami mengembangkan kesadaran yang lebih dalam tentang budaya, adat istiadat, berpikir dan gender yang berbeda untuk meningkatkan program sekolah.

Informasi Pribadi:

Anak (Inisial/Tanggal Lahir/Jenis kelamin) : _____ / _____ / _____ Lama bergabung dengan SMS : _____

Research Questions:

1. Apakah anda tahu semua peraturan di kelas? Pernahkah kamu melanggar aturan kelas? _____
2. Bagaimana perasaanmu jika melanggar peraturan di kelas? _____
3. Mana yang lebih disukai bermain bersama teman atau sendirian? Mengapa? _____
4. Apakah anda tahu tentang bullying? Apa itu? Dari mana anda tahu soal itu? _____
5. Pernahkah kamu mengalami atau melihat peristiwa bully? Apa yang kamu lakukan? _____

Chapter 42

MORAL DISENGAGEMENT AS AN ADAPTIVE STRATEGY IN THE FACE OF VIOLENT BEHAVIOUR AMONG PEERS

***Isabel Cuadrado-Gordillo^{*}, Inmaculada Fernández-Antelo
and Guadalupe Martín-Mora Parra***

Department of Psychology and Antropology,
University of Extremadura, Badajoz, Spain

ABSTRACT

Children's access to technological media and resources exposes them to new forms of communicating and relating which are characteristic of a dual society such as today's, but which they are not always prepared to handle. It is often observed that adults accompany youngsters' use of the new screens and access to Internet very little. All this has led to the emergence of novel forms of aggression that coexist with the more traditional forms, thus contributing to converting the victim's role to one of poly-victim. The present study's objectives were to: (1) identify and analyse the prevalence of poly-victims, and (2) determine how the levels of moral disengagement and the various defence mechanisms that victims use to explain abusive behaviour might function as predictors of poly-bullying. The sample consisted of 1328 participants of from 9 to 14 years old. The instruments used were two questionnaires. One, adapted from Cuadrado (2011) & Cuadrado and Fernández (2014), allows the prevalence of bullying and cyberbullying victims to be identified and analysed. It covers 8 modes of bullying in each of off-line and on-line scenarios. The other analyses the level of moral disengagement and the defence mechanisms to which the victims resort (Bandura, 1996). The results showed there to be a continuity of the role of victim in off-line and on-line contexts, turning those who are subject to these situations into poly-victims. The moral disengagement of these victims was found basically to be centred at two levels – a locus of behaviour, and a locus of outcomes. The commonest defence mechanisms used are moral justification and minimization of consequences. Finally, the results suggested that certain levels and mechanisms of moral disengagement may expose victims to a greater risk of suffering multiple abuses by their peers.

INTRODUCTION

After its emergence, the use and popularity of the Internet has extended to the point that it is difficult to conceive life without this virtual network. One of the main achievements that the Internet has brought is the creation of a space which, although not physical, is very real: cyberspace. Cyberspace surpasses physical and social limits, and blurs the norms defining when and how to interact. This virtual space has also created numerous cyberscenarios that have become the bases for the virtual relationships that have arisen in diverse and numerous social networks. Social networks and instant messaging applications allow users to interact socially either person-to-person or within groups. This is the case of the social networks that are most popular among teenagers and young adults: Facebook, Instagram, Twitter, and WhatsApp (Chang & Chen, 2014; Davenport et al., 2014; Lee, 2014; Reinecke & Trepte, 2014; Spies & Margolin, 2014).

The communications possibilities that these virtual tools have are huge, and they indeed have considerably expanded communicative exchanges between people. Research conducted in the United Kingdom has shown that 55% of children of 3 or 4 years old regularly use tablets and 24% use a computer or laptop. From 5 to 7 years in age, the proportions grow to 67% in the case of tablets and 49% for computers or laptops. They also start using smartphones. At ages 8 to 11, the percentages continue to increase: 80% for tablets, 66% for computers, and 32% for smartphones (Ofcom, 2016). Similar results have been found in North America (Pearson, 2015) and Spain, where around 93.8% of children and teenagers from 10 to 15 years in age have access to the Internet through the different technological resources they have available to them (Cuesta, Muñoz & Izquierdo, 2017).

Access to these tools from an early age is also exposing children and teenagers to dangerous situation, not only in physical contexts, but also in virtual ones, and which they often know little or nothing about. Inability to control the use children and teenagers make of the Internet and the lack of supervision by caregivers and parents are directly related to a series of negative consequences that have a direct influence on the daily lives of these young people (Spada, 2014).

Bullying, materialized as physical, psychological, emotional, and social mistreatment, includes such behaviour as derision, threats, insults, physical aggression, and isolation, inter alia. Additionally, with Internet and social networks, the digital society has made it possible for violent behaviour among peers to go beyond the physical context. In the cyberspace context, cyberbullying has recently become another phenomenon of a violent nature that is a cause of great concern, and consequently has already led to much research. This construct is materialized in threatening behaviour, insults, harassment, humiliation, etc., directed at peers through virtual media, whether using a computer, a mobile phone, or any other digital tool.

Previous studies have shown that different forms of violence tend to occur together, thus causing the traumatic events to overlap (Gustafsson, Nilsson & Svedin, 2009). Those who experience intra-familial and virtual victimization are therefore more likely to experience traumatic events in physical contexts outside the family (Fisher et al., 2015). The term “polyvictim” was coined in response to this trend. It is used to describe people who have

experienced more than one type of interpersonal violence (Finkelhor, Ormrod & Turner, 2007). In this regard, several studies have found that people who suffer from polyvictimization experience greater negative consequences in their lives than those who have had to bear a single negative stressor, even when that stressor is very serious or is repeated continuously throughout their life (Finkelhor, Ormrod & Turner, 2009). In addition, recent studies have found that there is a continuity in polyvictimization experiences from early childhood on through adolescence (Dierkhising, Ford, Branson, Grasso, & Lee, 2018).

CONCEPTUALIZATION OF THE POLYVICTIMIZATION PHENOMENON: CONSENSUS AND CONTROVERSIES

Approaches to the polyvictimization phenomenon still present important discrepancies concerning the number of forms of aggression suffered, and frequency or intensity of the abuse. In this regard, authors such as Finkelhor, Ormrod & Turner (2009) consider children who indicate having suffered at least four different forms of violence during the preceding year to be polyvictims. However, more recent studies have stopped identifying polyvictims on the basis of the sum of the violent episodes they have experienced, to focus instead on the person. Within this current, Ford, Grasso, Hawke & Chapman (2013), Havlicek (2014), and Matos, Moleiro & Dias (2014) distinguish different victimization experiences (physical abuse, assault, sexual abuse, etc.), also measuring potentially harmful situations and adversities. These studies also indicate that the same number of stressors on different victims can trigger very different problems. The impact that such events can have on polyvictims depends therefore on the particular combination of events, on the victimization, and on the adversities faced. The nature of the stressors will determine whether the negative effects are triggered by a single harmful event, or by a combination of several specific traumatic events.

Taking into account the kind of negative stressor the polyvictims face, some studies find that the severity of the negative consequences experienced and their association with the development of mental illness would be explained by the polyvictims' feelings of injustice (Forbes et al., 2014). When an event of this kind occurs, the victims feel that they have been betrayed and that the rules governing the world have been transgressed. This then generates in them a feeling that is different from that provoked by such traumatic events as natural tragedies or accidents, which have completely different causes.

Continuing with the polyvictims' perspective, other workers have explored the reasons that lead these persons to repeatedly experience this type of situation over time. In this respect, the focus of these studies seems to be Seligman's theory of learned helplessness (1975). This theory predicts that people who have been repeatedly exposed to uncontrollable negative stressors will be unable to cope with other subsequent negative controllable situations due to a general sense of helplessness that prevents them from acting. The victimization to which children and teenagers are exposed would therefore be the cause of their decreased ability to respond to the repetition of violent situations. To deal with these situations, teenagers tend to use such ineffective strategies as avoidance or denial, which only increase their stress and frustration (Guerra, Pereda, Guilera & Abad, 2016). While there is still much research to be done into the coping strategies that polyvictims use to stop and overcome the abuse they suffer, some studies seem to confirm Seligman's predictions (Steiner, Erickson, Hernández & Pavelski, 2002).

The origin of the aggressions and the age variable have also been addressed in research on polyvictimization. In this sense, Grasso et al., (2013) point out that polyvictimization in early childhood is associated with events that take place in the context closest to the children – their home. These traumatic events include witnessing physical or psychological domestic violence. Polyvictimization in early childhood also seems to be associated with the prolongation of this symptomatic situation through later stages of life (Finkelhor et al., 2007). Thus, 9 out of 10 children who experience polyvictimization during early childhood are still polyvictims later on in their life (Dierkhising et al., 2018), although the actual experience of the harm is less in children than in teenagers or adults (Radford, Corral, Bradley & Fisher, 2013).

During adolescence, polyvictimization may also be associated with events outside the family since it coincides with a period of time when teenagers begin to have a more varied and extensive social life, generally decentralized with respect to the family core. During these years, together with the familial traumatic events there needs to be added other events such as sexual assaults, street violence, bullying, cyberbullying, etc. This age group should thus be identified as that of greatest risk (Finkelhor & Dzuiba-Leatherman, 1994). These facts lead to a lower likelihood of being able to establish satisfactory relationships of trust during their lives, which in turn arrests or hinders the development of their self-esteem and self-confidence (Soler, Paretila, Kirchner & Forns, 2012).

Data on the prevalence of polyvictimization in the scientific literature differ depending on the tools and scales used. Cyr et al., (2013) analyse polyvictimization in a sample community of North American teenagers, finding a prevalence of around 10%, but Ford, Wasser & Connor (2011) obtain a prevalence of 32.5%. In Chile, Pinto & Venegas (2015) indicate that 41.9% of the teenagers they surveyed experienced more than one type of victimization throughout their lives. In northern European countries, some studies classify only 9% of their sample as being polyvictims (Ellonen & Salmi, 2011).

In Spain, recent studies have found different prevalences in different groups of polyvictims. Thus, Pereda, Abad & Guilera (2015) distinguish between low-level polyvictimization (15.2%) and high-level polyvictimization (4.1%), with the two groups together corresponding to a total of 20% polyvictimization. Additionally, that study indicates that 10% of the polyvictims remain polyvictims throughout their lives, perpetuating the negative effects. Dierkhising et al., (2018) note that almost one third of the children categorized as of low polyvictimization move to the high victimization group in later stages of their lives.

Regarding the prevalence of teenagers suffering from high polyvictimization, Cyr et al., (2013) note that 1% of teenagers have experienced 7 or more victimization experiences, while Finkelhor et al., (2005) raise this proportion to 7%. Subsequent studies carried out with different samples and tools indicate that 68.1% of a sample of 706 students suffered 6 experiences of interpersonal violence, and 30.3% 7 or more (Pinto & Venegas, 2015).

MORAL DISENGAGEMENT: CONNECTIONS WITH BULLYING AND CYBERBULLYING

The term moral disengagement was coined by Bandura, Barbaranelli, Caprara & Pastorelli (1996) to refer to the process or processes used to legitimize behaviour that goes against the beliefs, values, and norms of the victims. Moral disengagement consists of a series of cognitive

defence mechanisms that deactivate moral censorship and self-regulation with the aim of protecting self-esteem and self-concept. There are 8 defence mechanisms used in the process of moral disengagement:

- Moral justification, used to justify a questionable action as its having been carried out with appropriate motives.
- Euphemistic labeling, consisting in using indirect or ambiguous language to verbally minimize the severity of the objectionable actions carried out.
- Advantageous comparison, where the morally questionable action is compared with other worse actions performed before by other people.
- Displacement of responsibility, transferring the responsibility for the action carried out onto other people who have the necessary authority to order such actions, thereby legitimizing the act.
- Diffusion of responsibility, used to share the burden of the action over a group, and thus minimize the guilt that a single person would feel.
- Distortion of the consequences, consisting in diminishing the harm caused.
- Blaming the victim, in order to justify the action performed as a reaction to a previous reprehensible action by the victim.
- Dehumanization, reducing the human condition of the victim, and therefore their rights, thus making the behaviour carried out to not be so serious.

The aggressors' use of these mechanisms means that they have the possibility of legitimizing their violence as being standardized behaviour.

Within the context of school bullying, some studies indicate that children and teenage aggressors have higher levels of moral disengagement than those who are victim/aggressors, with those who are defenders being the group with the lowest degree of disengagement (Gini, 2006; Menesini, Fonzi & Sánchez, 2002). Similarly, those who express positive attitudes towards the actions of the aggressors have less moral engagement (Almeida, Correia & Marinho, 2010).

Studies focused on identifying and analysing specific moral disengagement mechanisms warn that aggressors accuse the victims of being mainly responsible for the situation they have lived through (Boulton & Underwood, 1992). In this sense, Camodeca & Gossens (2005) indicate that aggressors claim to feel anger when they commit an aggressive act, and that this anger is greater the more hostility they previously attribute to the victims' intentions. These results were confirmed and extended by Hymel, Rocke-Henderson & Bonanno (2005), who observed that the mechanisms most commonly used by teenagers of ages from 12 to 16 involved in these bullying situations are cognitive restructuring and blaming the victim.

With regard to moral emotions, various research studies have found that aggressors feel a greater number of moral disengagement emotions, such as indifference or pride in their actions. To this must be added the possession of fewer emotions related to moral responsibility, such as guilt or shame (Menesini et al., 2002). This translates into greater involvement of the aggressors in bullying situations since they perceive that their actions to be completely justified. Consequently, moral disengagement becomes a predictor of bullying (Barchia & Bussey, 2011).

In the virtual context, cyber-aggressors seem to show moral disengagement mechanisms that are similar to those manifested by physical aggressors. However, there are significant discrepancies between the results of different studies. Bauman & Pero (2011) and Perren & Gutzwiller-Helfenfinger (2012) find moral disengagement to be more consistently related to bullying than to cyberbullying, with the characteristics of the latter involving different moral mechanisms. But other studies affirm that moral disengagement mechanisms are equally linked to bullying and to cyberbullying (Robson & Witenberg, 2013). In this sense, Lazarus, Barkoukis, Ourda & Tsorbatzoudis (2013) find that moral disengagement is a predictor of cyberbullying. This fact is especially pronounced in teenagers who have low levels of moral reasoning, a characteristic that determines a stronger linkage between moral disengagement and the involvement as aggressor in cyberbullying episodes (Wang, Lei, Liu & Hu, 2016). More recent studies warn that cyber-aggressors have a higher level of moral disengagement than the rest of those involved in this type of situation (Larrañaga, Navarro & Yubero, 2018). These results confirm those of earlier research such as that of Meter & Bauman (2010).

Moral disengagement as a protection mechanism for self-esteem and self-concept is present not only in the aggressors but also in the witnesses of these violent behaviours. These latter adolescents tend to look for explanations for their inaction when observing morally reprehensible situations. The use of such defence mechanisms helps them to explain their inactivity as witnesses, which allows situations which are highly damaging for the victims to be perpetuated. Some studies have even found that witnesses tend to blame victims in the same way as aggressors do (DeSmet et al., 2012), denying that they themselves have any responsibility to intervene (Van Cleemput, Vandebosch & Pabian, 2014), and arguing either that mediation in these situations is a task that should be carried out by friends of the victim (DeSmet et al., 2012) or that the actions perpetrated are unimportant (Huang & Chou, 2010).

Recent research suggests that perhaps the key is related to collective moral disengagement which would have a mediating effect on individual morality, increasing or reducing the likelihood that witnesses will intervene. Allison & Bussey (2017) note that, when teenagers perceive that their peers are morally committed to intervene, they themselves tend to get involved more frequently.

A review of the scientific literature shows that studies of moral disengagement have been linked more to the role of aggressor than to that of witness. As far as we have been able to verify, there have been very few, if any, research studies focusing on the analysis of the processes of moral disengagement experienced by victims subjected to multiple forms of abuse. In this sense, the objectives of the present work were to: (1) identify and analyse the prevalence of polyvictims, and (2) determine how the levels of moral disengagement and the various defence mechanisms that victims use to justify abusive behaviour can act as predictive indicators of polyvictimization.

METHODS

Participants

In particular, we shall present the results of a study conducted in Extremadura (Spain) in which 1328 teenagers between the ages of 9 and 14 participated ($M = 12.3$, $SD = 1.1$).

Instruments

The instruments used for data acquisition were two questionnaires.

The first was an adaptation of the questionnaires of Cuadrado (2011), Cuadrado & Fernandez (2014) which were aimed at studying the prevalence of bullying and cyberbullying victims. The adaptation was based on integrating into a single instrument the questions aimed at identifying the victims of bullying and of cyberbullying. The forms of aggression contemplated for the analysis of off-line contexts are grouped into six categories: exclusion, verbal abuse, direct physical aggression, indirect physical aggression, threats, and sexual harassment. In the case of the on-line contexts, eight categories are considered: insults (including homophobia), threats (including blackmail), spreading false rumours (in order to harm the reputation, damage friendships, or to humiliate), exclusion (from contact lists, social networks, etc.), impersonation (another's identity is used to send or post material of insulting, inappropriate, or embarrassing content in order to damage the reputation or friendships of the victim), sexting, publication of denigrating images or videoclips, and recording and disseminating physical aggressions. For the study of each of these categories, questions were included relating to the use of different technological resources (i.e., chats, e-mails, forums, smartphones, social networks) through which these abuses were carried out. The participants had to answer these questions indicating the frequency with which they had suffered each category of abuse during the preceding two months. The scale used consisted of four values: never, once or twice, once a week, and several times a week.

The second instrument was the questionnaire published by Bandura et al., (1996). This reveals the moral disengagement mechanisms that the participants apply to themselves. They are grouped into eight categories: moral justification, euphemistic language, advantageous comparison, displacement of responsibility, diffusion of responsibility, distortion of consequences, attribution of blame, and dehumanization. The presence of one or a combination of these categories provides information about the processes of moral control and the selective location of moral disengagement as a function of the focus of the behaviour, the agent of the action, the outcomes that flow from the behaviour, and the recipient of the actions.

RESULTS

Identification of Polyvictims

The controversies that are found concerning the definition of polyvictimization make it difficult to determine the number of forms of abuse that a victim must undergo to be labeled a polyvictim. To overcome this obstacle, the prevalence of victims was calculated as a function of the number of forms of aggression suffered (Table 1).

Similarly, the analyses of prevalence depending on the frequency of abuse suffered has also been the object of numerous discrepancies. In face of this debate, we grouped the participants' responses into two categories: 'often', which would correspond to suffering aggressions once or twice in the preceding two months, and 'very often', which would encompass the frequencies of once a week and several times a week during the preceding two months.

Table 6. Prevalence of polyvictims depending on the contexts to which the aggressions belong

N° of forms of bullying suffered	Bullying polyvictims		Cyberbullying polyvictims		Bullying & Cyberbullying polyvictims	
	Often	Very often	Often	Very often	Often	Very often
2	196	47	245	91	382	128
3	79	15	168	37	235	72
4	8	2	49	16	149	51
5	1	-	11	3	92	27
6	-	-	7	1	78	15
7	-	-	-	-	51	10
8	-	-	-	-	28	3
9	-	-	-	-	3	-

In light of the results obtained, and in accordance with the most consensual position that we found regarding the number of forms of abuse a victim had to suffer to be considered a polyvictim, in the present study we shall identify as polyvictims the participants who felt they had been subjected to four or more types of abuse, regardless of the context in which these had occurred. Regarding the intensity or frequency of the aggressions suffered, and in accordance with the “repetition of aggression” criterion present in the conceptualization of both bullying and cyberbullying, we shall only consider as victims those participants who had been subjected to continued abuse. In our case, the instrument used quantifies the victims and polyvictims who have suffered abuse in the last two months with different degrees of frequency. Given that this is a very short time interval, we consider both those who have suffered abuses “often” and those who have suffered them “very often” to come within the category of polyvictim.

The results reveal, on the one hand, the continuity between the off-line and on-line contexts in victimization processes. The prevalence data show a remarkable coexistence of the bullying and cyberbullying phenomena. In particular, there were more victims and polyvictims in this convergence of contexts than in each separately (Table 1). And on the other hand, we observed that the aggressions suffered through technological means surpassed those registered in face-to-face contexts. Together with other factors, the ease with which aggressions spread in the cybernetic world and the possibilities of anonymity the aggressors make use of when abusing other people without suffering reprisals would explain the tendency to use cyberspace as a channel through which to commit aggression, and therefore the greater number of cyberbullying than bullying victims. Likewise, the results show a significant decrease in the number of victims and cybervictims when the forms of abuse are experienced 'very often', regardless of the context in which these aggressions occur.

Finally, as the number of forms of aggression increases, the number of victims decreases. Narrowing the results to the participants who had suffered four or more forms of abuse, the prevalences were the following: bullying polyvictims 0.8%, cyberbullying polyvictims 6.5%, and bullying and cyberbullying polyvictims 38.2%.

Variations in the Polyvictims' Use of Moral Disengagement Mechanisms

A descriptive analysis shows the variability of moral disengagement mechanisms used by the different groups of polyvictims, taking into account the origin of the aggressions they had received (Table 2).

The results reveal that the moral disengagement mechanisms most used by polyvictims are moral justification, distortion of consequences, use of euphemistic language, and minimization of the consequences. The moral disengagement is at the lowest levels in the use of mechanisms related to dehumanization of the victim and blaming others (Table 2). The highest scores in the aforementioned mechanisms show that the polyvictims' moral disengagement is basically founded on two levels: control of the behaviour, and control of the result.

We observed differences between the mechanisms used by the different groups of polyvictims. In this case, however, one must speak of just a tendency towards various uses, since the great inhomogeneity in the sizes of the groups undermines the significance of those differences.

Specifically, the results show that the group of cyberbullying polyvictims scores higher than the other two groups in all the moral disengagement mechanisms (Table 2). This reflects higher levels of moral distortion that can lead to problems of greater severity, as well as to the persistence of the role of polyvictim and its possible transfer from physical to cybernetic contexts.

Table 7. Mean scores of the moral disengagement mechanisms used by the polyvictims

Moral disengagement mechanisms	Bullying polyvictims		Cyberbullying polyvictims		Bullying & Cyberbullying polyvictims	
	Mean	SD	Mean	SD	Mean	SD
Diffusion of responsibility	2.40	0.70	2.48	0.63	1.96	0.61
Displacement of responsibility	2.59	0.78	2.70	0.72	2.63	0.72
Euphemistic labeling	2.64	0.68	3.05	0.77	2.96	0.79
Advantageous comparison	2.71	0.73	3.15	0.82	2.89	0.74
Distortion of consequences	2.68	0.71	3.26	0.84	3.09	0.81
Dehumanization	1.15	0.40	1.26	0.42	1.19	0.42
Attribution of blame	1.67	0.51	1.73	0.56	1.65	0.51
Moral justification	2.93	0.74	3.10	0.83	2.89	0.80

Focusing on the group with the highest percentage of polyvictims, we are able to analyse whether the number of different forms of aggression suffered has any influence on the use of some particular moral disengagement mechanisms. In order to roughly equalize the distribution of the groups, we constructed three categories in terms of the number of forms of aggression suffered: 4, 5-6, and >6 (Table 3).

The results revealed that there were statistically significant differences among the polyvictims subjected to a greater or lesser number of forms of aggression in six of the eight moral disengagement mechanisms analysed (Table 3).

Table 8. Differentiation of bullying and cyberbullying polyvictims' use of moral disengagement mechanisms

Moral disengagement mechanisms	N° of forms of bullying suffered	Mean	SD	F _(3,107)	Sig
Diffusion of responsibility	4	2.23	0.67	5.311	0.039
	5-6	2.04	0.65		
	More than 6	1.81	0.61		
Displacement of responsibility	4	2.76	0.70	4.685	0.048
	5-6	2.67	0.75		
	More than 6	2.51	0.71		
Euphemistic labeling	4	2.87	0.78	28.143	<0.001
	5-6	3.02	0.80		
	More than 6	3.28	0.77		
Advantageous comparison	4	3.11	0.77	32.015	<0.001
	5-6	2.96	0.75		
	More than 6	2.74	0.71		
Distortion of consequences	4	3.38	0.84	18.136	0.041
	5-6	2.80	0.79		
	More than 6	2.91	0.79		
Dehumanization	4	1.07	0.40	2.004	0.182
	5-6	1.28	0.45		
	More than 6	1.15	0.42		
Attribution of blame	4	1.55	0.48	2.684	0.145
	5-6	1.72	0.53		
	More than 6	1.66	0.51		
Moral justification	4	2.68	0.83	19.489	0.029
	5-6	2.74	0.76		
	More than 6	3.01	0.81		

In particular, as victims suffer more forms of aggression they more frequently resort to mechanisms of euphemistic language ($p < 0.001$) and moral justification ($p < 0.05$). However, in the use of the diffusion of responsibility ($p < 0.05$), displacement of responsibility ($p < 0.05$), and advantageous comparison ($p < 0.001$) mechanisms, the trend is reversed, with those who make more use of them experiencing fewer forms of aggression. We obtained a similar result in the analysis of the distortion of consequences mechanism ($p < 0.05$), although those who suffer more than six forms of aggression usually employ this mechanism more than those who suffer 5 or 6 forms. Nonetheless, the differences between these two groups were not very pronounced.

CONCLUSION

This study has addressed a subject about which there still remain many questions to be answered. Previous studies have inquired into the possible causes leading a teenager to become an aggressor, finding moral disengagement to be a variable worthy of consideration. However, the relationships between moral development and victimization have often been pushed into the background, making any thorough analysis of the factors that intervene in the permanence of the role of victim difficult. The present results have shown that child and teenage victims of

peer abuse experience different levels of moral disengagement that may be able to explain how victims who have been abused in physical contexts also become victims in cybernetic contexts. These distortions in the development of morality may equally be leading to a greater number of forms of aggression suffered, so that the victim becomes a polyvictim, with all the aggravating factors that this label entails. In this sense, we consider that the data provided by this study open the way to new lines of research that urgently need to be explored and addressed.

The positive relationship found between moral disengagement and the condition of victim or polyvictim, in both off-line and on-line contexts and contexts in which the two coexist, reflects a situation of victims resorting to self-incrimination as a cognitive resource allowing them to justify the aggressions they have been subjected to. This fact reminds us of the postulates of the Stockholm syndrome, and would explain why the victims persist in enduring an abusive environment.

Among the contributions of this study, there stands out the analysis that was carried out in three different contexts, detecting the polyvictims and investigating the use they make of different moral disengagement mechanisms. The results showed that bullying in off-line contexts has been declining markedly, and has moved to the virtual, on-line context in which the aggressor can hide his or her identity, the harm done to the victim can be greater as a result of the rapid and widespread dissemination of the abuses suffered, and the victims' perception of helplessness is greater. In our results, fewer than 1% of the participants were definable as polyvictims of bullying, with this proportion increasing to more than 6% when dealing with polyvictims of cyberbullying.

However, the coexistence of two different worlds in which we operate in parallel, the off-line and the on-line worlds, has led to a new profile of victim resulting from the continuity of aggressions experienced in physical contexts passing into cybernetic contexts. The child or adolescent who is subjected to abuse by their peers in school probably also suffers abuse through technological media, thus becoming a cybervictim (Cuadrado & Fernández, 2016). Experiencing abuse in the two contexts allows there to be more forms of aggression that they might suffer, and hence an increase in the prevalence of bullying and cyberbullying polyvictims.

With regard to the moral disengagement mechanisms that the different categories of victims use, the most used were moral justification, distortion of consequences, use of euphemistic labeling, and minimization of the consequences. All of these are oriented towards lessening the importance of the actions that they have had committed against them and of the consequences deriving from those actions. These data provide information that is invaluable for the design and implementation of measures and programs for the prevention of, and intervention against, violence amongst peers, and especially against the durability of the role of victim or polyvictim.

The results confirm that some moral disengagement mechanisms are prioritized over others as a function of the number of forms of aggression the victim suffered. Those who have been subjected to more than six different forms of abuse tend to distort the actions committed against them by using language that masks or downplays the form and the seriousness of the aggression, as well as the harm it causes. They also resort to arguments that try to explain, justify, or even validate aggressive behaviour by showing that behaviour to be appropriate to the circumstances and moments it occurs.

Those who have been subjected to just four forms of aggression, however, tend to prioritize moral disengagement mechanisms that are related to the diffusion or transfer of the aggressor's

responsibility, or to comparing their situation with more serious situations that are experienced by others. In these cases, the victims are trying to palliate the pain and helplessness they feel by attributing responsibility to the strength of a group or of a person perceived by others as being impossible to stop or control due to their being attributed power, popularity, or exaggerated authority. These victims interpret their own situation as being bearable, acceptable, or even advantageous in comparison with the painful or traumatic experiences that other people may be suffering.

While these distortions may at first play the role of defence mechanisms, they nevertheless contribute to perpetuating the role of victim and favour the processes of polyvictimization.

In sum, one of the principal contributions of the present study is its approach to understanding the cognitive distortions that polyvictims use to justify the abuse they suffer, and the information it has provided is a key to going in greater depth into the causes of the perdurability of the role of victim and its transformation into that of polyvictim.

Chapter 43

BULLYING AMONG HEALTH CARE PROVIDERS

Sergey Pisklakov, MD, Ming Xiong, MD and Anuradha Patel, MD

Department of Anesthesiology and Perioperative Medicine, New Jersey Medical School,
University of Medicine and Dentistry of New Jersey, Newark, US

ABSTRACT

Bullying is defined by American Psychological Association as an aggressive behavior which is intended to cause distress or harm and that involves an imbalance of power or strength between the aggressor and the victim. Bullying in the workplace is angering enough people these days to be fueling a nationwide grass-roots legislative effort to force companies to draft and enforce policies aimed at stopping it. Requiring such policies, according to those pushing the legislation, is not an attempt to spawn lawsuits, but an effort to force organizations to deal with the problem. Bullying is blamed for unnecessarily creating high costs of turnover, insurance claims and thwarted productivity. Disruptive behavior has been observed in almost all members of the healthcare team from physicians and nurses to pharmacy, radiology, and laboratory staff members. Physician behavior, however, may have the greatest impact because of the position of authority that doctors hold as members of the healthcare team. A team member may, from fear of intimidation or patronization, withhold valuable or even critical input, such as a medication error or a breakdown in adherence to safety protocols. Hospitals, departments and individual personnel need to develop a higher level of awareness of the problem both in others and in them. Anti-bullying policies should be given a higher profile.

This Bullying is defined by American Psychological Association as an aggressive behavior which is intended to cause distress or harm and that involves an imbalance of power or strength between the aggressor and the victim. A more objective if somewhat wordy definition used by Swedish workers is that bullying emerges when one or several persons over a period of time persistently perceive themselves to be on the receiving end of negative actions from one or several persons in a situation where the one at the receiving end has difficulty in defending him or herself against these actions. This definition incorporates the subjective feelings of the person on the receiving end, even where an individual may have behaved aggressively but with no intention to harm. It puts an onus on each individual to be mindful of the effect of their actions on others. It does not offer protection to those falsely accused of bullying. The main

features of this definition are negative behaviors, persistence over time and an imbalance of power (Einharsen et al., 1994). Bullying can be physical, relational, peer sexual harassment and stereotyping. It is a way to gain power (Kozłowska et al., 1997). Bullying in the workplace is angering people these days. It is fueling a nationwide grass-roots legislative effort to force companies to draft and enforce policies aimed at stopping it. Requiring such policies is not an attempt to spawn lawsuits. It is an effort to force organizations to deal with the problem. Bullying is blamed for unnecessarily creating high costs of turnover, insurance claims and thwarted productivity (Rosenstein & O'Daniel, 2005).

In January 2009, a new standard issued by the Joint Commission [formerly JCAHO] went into effect. It requires hospitals to have “a code of conduct that defines acceptable, disruptive, and inappropriate staff behaviors” and for its “leaders [to] create and implement a process for managing disruptive and inappropriate staff behaviors.” The rationale for the standard states: “Leaders must address disruptive behavior of individuals working at all levels of the [organization], including management, clinical and administrative staff, licensed independent practitioners, and governing body members.” A Joint Commission sentinel alert includes “uncooperative attitudes” and “condescending language or voice intonation and impatience with questions” as disruptive behaviors. The Joint Commission’s first-ever alert about the problem is the latest industry effort to address an issue that has challenged the medical community for years (The Joint Commission, 2009). Suggested actions include systems to detect and deter unprofessional behavior; more civil responses to patients and families who witness bad acts; and overall training in “basic business etiquette,” including phone skills and people skills for all employees (Joint Commission Sentinel Event Alert, 2008). Administrative response to bullying has been so far ineffective. In some cases no action was taken. This lack of action could lead to serious liabilities since these incidents are not only about bullying, but also sexual harassment and discrimination. Disruptive behavior has been observed in almost all members of the healthcare team—from physicians and nurses to pharmacy, radiology, and laboratory staff members. Physician behavior, however, may have the biggest impact because of the position of power that doctors hold as members of the healthcare team (Quine, 2002). A team member may, from fear of intimidation or patronization, withhold valuable or even critical input, such as a medication error or a breakdown in adherence to safety protocols (Rosenstein, 2005). To ensure good patient care and respect among all healthcare professionals is at the very foundation of the ethics advocated by the American Medical Association. Intimidating, condescending, off-putting, or discouraging behavior by the physician inhibits positive team work. If OR staff works sub optimally because of disruptive behavior by the physician or another team member, overall care quality is compromised and patient safety is threatened. To mitigate these risks, healthcare organizations must re-examine their hospital harassment policies to ensure those policies include specific prohibitions against gender discrimination and harassment. Hospitals also need to create a workplace conduct policy forbidding bullying or harassment regardless of gender. Once policies are in place, comprehensive training courses should be given to all supervisors and physicians. When policies violated, action should be taken.

Bullying is a form of aggression. Physical bullying is obvious in our society. It tends to be the province of children. Adults are more subtle and devious in their approach, and their bullying can take a variety of forms, many of which may not be obvious to a third party. This allows bullies to continue their activities unchecked and enables them to do what they wish (Paice, 2004). The outburst in the OR by a surgeon or anesthesiologist is not uncommon.

Misconduct against nurses is common (Uhari, 1994). Bullying and mistreatment during training is also a part of the experience of many doctors, medical students or residents (Quine, 2002). Psychological abuse, gender discrimination, and sexual harassment were prevalent in one study (Stratton, 2005). Nursing staff have been implicated in intimidating and harassing residents by verbal comments (Farrell, 1999; Coverdale, 2005); senior residents have also been implicated (Cohen, 2008; Cook, 1996; Daugherty, 1998). Of course, sometime excessive mentorship can be misinterpreted by trainee as bullying. An individual's personal beliefs and lack of self confidence colors their interpretation of any communication; criticism may be inferred where none was implied. Curt behavior by senior doctors may be interpreted as criticism by juniors even when this was not intended. Where the recipient of certain critical or aggressive behaviors is more junior and therefore constrained in their perceived ability to respond to it, this can be a problem (Moscarello, 1994). A bully tends to be in a position of relative power. This allows him or her to behave towards one or many others in an unacceptable way. This can be as simple as making it impossible for subordinates to progress up the career ladder by ensuring that they are not given opportunities (Cohen, 2008). Bullies may prevent a subordinate from developing their ideas, and develop them as if they were their own. They may manipulate subordinates to take on unacceptable commitments by playing on their vulnerabilities. The bullies may be perceived as good managers because they get more work done. In the medical world, bullies may avoid taking their fair share of unpleasant tasks in a department. They may do this by offloading some of these tasks onto others who are powerless to protest. If the affected individual does complain, the bully may threaten to activate certain sanctions within their power, to which the victim is vulnerable (Daugherty, 1998). The situation is like that of blackmail. It is not that the victim cannot complain; it is that they perceive themselves as helpless (Cook, 1996; Kozlowska, 1997). Often bullying is an extension of forms of negative behavior frequently seen in the medical world (Carr, 1997). When and where does it cross the line? Is there then an acceptable level of bullying? Awareness of bullying as a problem has increased, and there is evidence that the prevalence is high in medicine. Nevertheless, there is also the possibility that the behavior experienced by some as bullying is perceived by others as normal (Ahmer, 2009; Quinne, 1999, 2002).

People who are accused of bullying fall into two groups. The first group is those who intend to hurt and humiliate their victim, and who choose their victim with a view to getting pleasure from their power over them. This is uncommon. The second group is made up of people who perceive their behavior as reasonable, while the victim perceives it as bullying. When individuals in this latter group are accused of bullying they are often mortified and suffer a major blow to their self-esteem. Problem situations for this second group often relate to a senior/junior interaction. There are several reasons for this. In the past, senior role models may well have shown bullying behaviors. Many senior doctors are focused, dedicated and, at times, obsessional individuals who do not suffer fools gladly. They are often very self-critical. They expect equal levels of self-criticism, dedication and focus from their junior staff. Where the levels of activity they require from trainees are outside the normal range they are likely to be accused of bullying (Paice, 2004; Daugherty, 1998). Another category of bully is the medical manager. Frequently, they have been given little training for the task in hand and the demands of the system are often unrealistic. A proportion of these doctors, under pressure, may resort to any method by which they can achieve results, even if this amounts to bullying (Houghton, 2003). Bullying is still part of the organizational culture. For example, even though junior doctors' hours have been agreed, there is, in some specialties, pressure to arrive early and leave

late, irrespective of the amount of work to be done. Lastly, even normally amiable senior doctors may behave badly when under personal or professional stress (Johnson, 2009; Roberts, 2009).

One of the reasons is the lack of training for doctors and sometimes other managers in management or leadership skills. They simply may not appreciate that people are different (Daugherty, 1998). Absence self-criticism may exacerbate bullies' reaction to the confrontational situation. Very self-critical people become depressed, while individuals with low levels of self-criticism have problems in relationships with patients and colleagues (Paice, 2004; Daugherty, 1998).

Victims of bullying often believe that a complaint would negatively affect their professional progress, and with an intentional bully this might be the case. Thus, incentives to complain are outweighed by the perceived incentives to keep quiet (Margittai, 1996). This creates a "survival" culture, not too far removed from that of prison or the armed forces. The consequences of bullying are devastating. Bullying is responsible for victims becoming stressed, depressed and intending to leave their jobs. The 2004 study reported that 37% of doctors in training had been bullied in the past year (Uhari, 1994). Although there would appear to be a difference between intentional and unintentional bullying, the initially unintentional violator may gain satisfaction or results from this form of behavior, which will then be reinforced. Intentional bullying is a dysfunctional form of behavior which needs intervention and help (Cohen, 2008). Approaches to unintentional bullying should be both educational and organizational. Work with the individual accused of bullying may need to include psychotherapy to explore the reasons for bullying or aggressive behavior. It should also include work on interpersonal and self-awareness skills so that the bully can explore and adopt alternative ways of behaving (Houghton, 2005). This approach, while emphasizing that bullying is unacceptable, also recognizes that bullying behavior may be understandable and that those using it need help to change (Einarsen, 1994). The organizational culture also needs to change. Many companies have put in place clearly defined written policies to prevent bullying and harassment at work, but the problem persists. Management pressures, which essentially amount to bullying, may compel senior doctors to take on impossible clinical loads or to work in unacceptable facilities. They may in turn adopt bullying behavior with subordinates in response to these pressures. The problem may also persist because, although there is more general awareness of the problem, many victims still do not speak out, for a variety of reasons. One appalling truth is that some of these individuals have such low self-esteem that they do not recognize their treatment as bullying (Kozłowska, 1997; Johnson, 2009).

Hospitals, departments and individual personnel need to develop a higher level of awareness of the problem both in others and in them. Anti-bullying policies should be given a higher profile. This should encourage victims to come forward so that individual bullies can be identified. The unintentional bully will usually, although not always, respond to the strategies outlined above and modify their behavior. They may well respond to personal approaches on the part of the victim. Direct approach of the bully may be counterproductive. The victim should keep a careful record of all behavior they perceive as bullying. It is important to ascertain that what you dealing with are bullying. Once confirmed that you are dealing with bullying, you should approach the bully's line manager or the human resources department. Finally, you could also approach your professional association for advice and support (Houghton, 2004).

We know little about how verbal abuse or bullying is triggered and how it might be prevented (Farrell, 1999). Primary preventive methods include providing educational materials and communication skills training for residents, staff, and educators (Baldwin, 1991). Education on abuse, discrimination, and harassment in the workplace, and how these can be addressed and averted, can also be presented in formal and informal curricula. Such initiatives should promote culture of collegiality and respect for all faculty, staff, and trainees (Quine, 1999). Secondary preventive measures rely on reporting mechanisms. Any occasion of abusive or discriminatory language or behavior needs to be addressed. Measures such as debriefing and supportive counseling should aim to alleviate the psychologically distressing consequences of these behaviors for all recipients and observers. Universal focus on professionalism in medical education and professional behavior of physicians in practice should help us to eradicate this unacceptable behavior (White, 2000).

Chapter 44

CYBERBULLYING

Caleb McCoy, Marisa Potate and Cliff McKinney*

Mississippi State University, MS, US

ABSTRACT

Bullies are individuals who use a superior force, whether it is physical or mental, to assert dominance over others in an effort to do what they ordinarily wouldn't. Recently, technology has become a fundamental part of life. People can't seem to escape technology without having to cut off all communication from the world. Access to the Internet has become more readily available through new technology such as tablets and mobile phones. As the need for physical communication decreases, use of cyberbullying as an alternative form of traditional bullying has become devastatingly prevalent. Cyberbullying is becoming more frequent throughout the world with advances in technology rapidly changing the traditional definition of bullying. Cyberbullying has become a way for those who typically would not bully, to terrorize without consequence, so it is not only affecting those who would have traditionally bullied, but it is also affecting a broader range of individuals including all ages through childhood, adolescents, and adulthood. Those who are bullied generally show more cognitive and affective empathy. Further, students who have pro-victim attitudes (i.e., the belief that bullying is unacceptable, victims are acceptable, and defending victims is valued) are less likely to be bullied than other students. Unfortunately, there are many dimensions to cyberbullying that make it easier to attempt than traditional bullying. One of these is the absence of physical strength. Those who were not strong enough to bully in a traditional setting, find it easier to bully via the Internet. Cyberbullying also decreases the level of awareness of the victim's distress. Another factor that makes cyberbullying easier is the ability to be anonymous to some extent over the Internet. There is a method of indirectly bullying people over the Internet as well. By tortuously posting a picture or statement on a social media page, cyberbullying can directly affect the victim without the bullying needing to target a specific person. Further, there is a lack of fear in cyberbullies, and they are often unaware or less aware of the consequences for their behaviors. Some cyberbullying attempts are even based on the ability of a teacher to intervene on traditional bullying attempts giving the bully an outlet with fewer consequences. Cyberbullying has the same side effects and consequences as traditional

bullying. Low self-esteem and depression have been more consistent in victims rather than non-victims. In the past, bullying took place in specific environments such as school, work, home; places that are supposed to offer a sense of safety. Cyberbullying completely diminishes the idea of safety for victims of bullying. Victims are often unable to find a place of security due to the accessibility of technology and other people. However, many programs and organizations have worked to put an end to bullying by implementing constant awareness and guidelines within schools, workplaces, and social media.

In general, children are seen as the most prominent source of internet bullying. Although they are not the only age group that can be a source of cyberbullying, most of the research in cyberbullying has been done on this age group. Children and adolescents in the present have been raised as part of an internet generation. However, children and adolescents aren't the only age group affected by cyberbullying. Adults have also been involved with sides; bullying and being bullied with the use of social media and technology. Therefore, it is of great importance to note the amount of cyberbullying that occurs among children, adolescents and adults. In this paper, cyberbullying will be compared with traditional bullying by reviewing the similarities, differences, perceptions, and characteristics of multiple forms cyberbullying. Also, this paper will discuss a few cases that involved victims of cyberbullying, and prevention plans that have recently been added to intervene.

SIMILARITIES AND DIFFERENCES BETWEEN CYBERBULLYING AND BULLYING

First, it is of great importance to point out that cyberbullying is much different than traditional bullying. Although there is not a completely agreed upon definition of cyberbullying, it definitely lacks some components of traditional bullying that may have aided in decreasing ambiguity among the perpetrators and victims. For example, cyberbullying contains text that maybe easily misunderstood with no other types of communication to assist in meaning. When body language and eye contact are not taken into account, words can be easily twisted into different meanings than what was originally intended (Baruch, 2005). Because of this, cyberbullying can be much harder to identify than traditional bullying styles. Furthermore, text on the internet or through mobile devices may stay in cyberspace for unlimited amount of time or until someone takes the comments down, but the text may have gone viral at that point. There is no way to know for sure where text may end up on the internet. Spoken words may disappear, but hurtful comments through cyberspace may have a longer effect. In addition to this, some researchers are in disagreement as to whether or not this should be counted as repetition due to its lasting effect (Slonje & Smith, 2007). Another factor in cyberbullying that is different than in traditional bullying is that there is a certain amount of anonymity that comes with being a cyberbully.

Unfortunately, cyberbullies can mask their identities a number of different ways on the internet. A traditional bully may find masking themselves difficult. In fact, traditional bullies generally bully on the basis of physical strength whereas cyberbullies do not worry about appearance. Instead, they are able to focus more on emotional strength, ease of manipulation, and dominance (Ybarra & Mitchell, 2004). Further, the lack of exposure creates an environment where the bully has little chance of developing skills such as empathy because there are no

consequences for the bully (Froese-Germain, 2008). This is contrary to traditional bullying where the bully is face to face with the victim. Even though cyberbullying is much different than traditional bullying, it is also similar when it comes to the motive for attempting to cyberbully someone else. The motive behind traditional bullying is generally to cause distress to another person because of jealousy or dislike. The motive for cyberbullying is generally the same.

CHARACTERISTICS OF CYBERBULLY PERPETRATORS AND VICTIMS

As far as a profile for child and adolescent cyberbully victims, a definite profile has been unclear. Some researchers claim that there is no significant difference between the rate of cyberbullying toward boys and girls (Li, 2006; Patchin & Hinduja, 2006; Slonje & Smith, 2007). Some other research has shown that girls may be more prone to being cyberbullied than boys are (Li, 2007; Smith, Mahdavi, Carvalho, & Tippet, 2006). This difference could possibly be due to demographic differences as well as several other factors. Another factor that has been disagreed upon in the literature is age. Some research has shown that the chances of being cyberbullied increases with age (Kowalski and Limber, 2007; Patchin and Hinduja, 2006). Some has shown that there is a decrease in the chances of being cyberbullied as children and adolescents grow older (Slonje & Smith, 2007). Still other research has shown that there has been neither an increase nor a decrease in cybervictimization as children grow older (Smith et al., 2006, 2008). Still other research has shown that the ages in which cyberbullying seems to be the biggest problem are ages 11 to 18 years (Baumand, 2007).

Further, there are many characteristics of internet usage that may play a role in cybervictimization or perpetration. Li (2007) found that there was no link between the amount of time spent on the internet and the amount of time users bullied or were victimized by bullies. However, Ybarra (2004) found that the amount of time on the internet and the use of instant messaging were significantly correlated with cybervictimization among females. Ybarra (2004) also found that the amount of internet use in males was a small predictor for internet harassment. Patchin and Hinduja (2006) had similar results, and they found that those who spent more time on the internet were more likely to experience online bullying. Juvonen and Gross (2008) even found that webcam use was correlated with a higher risk of repeated cyberbullying.

In addition to these characteristics, some studies also have shown that different psychological characteristics may have a relationship to cyberbullying. Unfortunately, it is difficult to tell whether these characteristics are causes or symptoms of cyberbullying. 42.5% of cyberbullying victims felt frustrated according to Patchin and Hinduja (2006). Similarly, 40% felt angry and 27% felt sad. These figures could be due to the fact that cyberbullying can cause these problems, but it is also possible that these individuals have these characteristics already, making them more susceptible to cyberbullying and even traditional bullying. One study of males found that they were 8 times more likely to be bullied if they had depressive symptoms (Ybarra, 2004). Also, Juvonen and Gross (2008) conducted a study where a positive relationship was shown between social anxiety and cyberbullying. Most of these studies also found that those who were prone to being bullied in the traditional style were also prone to

being bullied through cyberbullying in up to one out of three cases (Deheu & Bolman, 2008; Juvonen & Gross, 2008; Li, 2007).

PERCEPTIONS OF CYBERBULLYING

Cyberbullying clearly is a big problem, but it is unclear whether the perceptions of cyberbullying reflect this throughout each generation. In one study of children (Vandebosch & van Cleemput, 2009), when asked if they had been involved with cyberbullying, 11% said that they had been cyberbullied, 18% admitted to being the perpetrator in a cyberbullying situation, and 27.9% said that they were bystanders to a cyberbullying attempt. Further, 63.8% of respondents considered cyberbullying to be a big problem. These numbers come from when respondents were asked directly if they had been involved in bullying. However, when students were asked questions about specific types of cyberbullying but the word bullying was not used, there was a much greater response. It showed that 61.9% had been victims, 52.5% had been perpetrators, and 76.3% had been bystanders. On average, about 20% of people perceive themselves to be the victim of cyberbullying, but the reality is, that cyberbullying occurs much more often than that.

One of the most important factors of Cyberbullying is the perception of it by those who are perpetrators, victims, and bystanders. Many times, teachers are aware that cyberbullying and do not know how to effectively stop it from happening. One of the most difficult problems that administrators and educators face is the not infringing on first amendment rights by punishing students for cyberbullying that occurred outside the school (Willard, 2007). One study found that even when anti-bullying campaigns are promoted in schools, they are not necessarily effective (Ferguson, Miguel, Kilburn, and Sanchez, 2007). Many researchers have found that it is extremely difficult for a school to implement programs that effectively reduce cyberbullying (Merrell, Gueldner, Ross, & Isava, 2008; Smith, Schneider, Smith, & Ananiadou, 2004).

ONLINE GAMING

A newer realm to cyberbullying has become an increasing problem: online gaming. This method is not as anonymous as some other methods (i.e., the cyberbully may have an identifiable in-game avatar), but can still give the perpetrator a sense of superiority over the victim. With the use of screen names or avatars instead of real names or face-to-face interactions, it is completely possible for a perpetrator to remain anonymous if they feel that it is necessary (i.e., a perpetrator can create multiple avatars ensuring anonymity). Unfortunately, online gaming has become one of the most popular leisure activities for adolescents (Gross, 2010), so it may be easier for a perpetrator to victimize youth playing these games. Also, the aggressive nature of video games may play a role in increasing aggression (Huesmann, 2010), which could be referenced to the observational learning theory proposed by Bandura (1973). Some video games even reward aggressive behavior (Polman, Orobio de Castro, & van Aken, 2008), and video game addictions have been associated with aggressive behavior (Anderson et al., 2010).

Video games have become one of the most popular leisure activities among adolescents. Because they are being exposed more to video games, they are also being exposed to what is included in the video games. Most video games contain aggression in some form. It has been concluded that video games promote aggression through observational learning (Bandura, 1973; Huesmann, 2010). Not only do video games promote cyberbullying, but they may also play a role in promoting traditional bullying through exposure to violence and aggression. Those who engage in violent video games are less likely to show empathy and are more likely to show aggressive tendencies (Anderson et al., 2010). Unfortunately video games may be to blame for much of the cyberbullying and traditional bullying that occurs among youth.

ADULT CYBERBULLYING

Unfortunately, cyberbullying may even continue into adulthood. There has not been nearly as much literature on cyberbullying in adults as there has been on children and adolescents. Some researchers have tried to fill the gap in the literature, but there is still much to learn. Although the motives of bullying at this age are similar to those of younger children and adolescents and generally stem from jealousy and dislike, there are many more reasons that a person might be bullied. Another motivation for young adults to cyberbully is “trolling” or using cyberbullying as entertainment. One study found that up to 30% of adult perpetrators cyberbully purely for entertainment purposes (Rafferty & Vander Ven, 2014). One of the most common reasons for an adult to be cyberbullied or deal with cyber aggression is sexual orientation. One study explains that an increase in use of smart phones and social media by adults may be a cause for an increase of cyberbullying in adults (Lenhart, Purcell, Smith, & Zichuhr, 2010).

Among adults, cyberstalking seems to be a more prominent form of cyberbullying. Recent studies have shown that cyberstalkers tend to be more educated, struggle with internet addiction and are over the age of 16, which means that cyberstalking is much more prevalent among adults than children and adolescents (Reyns et al., 2012). Furthermore, cyberbullying in the workplace has become more common as technologies in businesses have advanced. One earlier study by Finn (2004) found that 10-15 percent of adults were victimized by some type of cyberbullying. Those numbers have increased greatly since that point. Walker, Sockman, and Koehn (2011) found that 56 percent of young adults had been victimized on social media sites like facebook, and 45 percent of young adults had been victimized through cell phones.

ADAPTATION OF BULLYING WITH TECHNOLOGY AND SOCIAL MEDIA

With the development of technology rapidly growing in today’s society, technology has worked its way into our daily tasks. Landline phones, dial-up Internet, and bulky desktop computers have been replaced by cellphones, Wi-Fi, and tablets. As these devices become more accessible, the use of them as tools to bully has increased also. In the 1980s, the words “YouTube,” “Facebook Post,” and “Tweet” did not exist, but these words are almost inescapable in conversation presently among adolescents. These are only a few examples of social media that have affected the way traditional bullying has progressed. Traditional bullying

required for the bully to be physically present to torment and manipulate the victim. However, with cyberbullying, the bully can be anywhere using technology and social media to manipulate the victim. Cyberbullying has been described as being cruel to others by sending or posting harmful material or engaging in other forms of social aggression using the Internet or other digital technologies (Willard, 2007).

There are many ways for bullies to use social media and technology to victimize. Willard (2007) explains 8 forms of cyberbullying. The term "flaming" is used to describe an online altercation using aggression and profanity. Flaming is not restricted to online social media such as Facebook and Twitter, but can also be done via text messaging and email. Once again, with the use of technology, people are able have arguments with each other without having to be physically present and without having to vocalize their aggression. If flaming develops into a common occurrence from the bully it becomes an even more problematic. "Harassment" is the repetition of sending vulgar and insulting messages after the initial situation(s) have occurred. This is seen in both traditional bullying and cyberbullying. The bully or bullies continually badger the victim(s) until they become submissive and more vulnerable. Both flaming and harassment can be unnoticed by other parties due to the lack of publicity. However, harassment can be made public directly and indirectly. "Denigration" is using social media to disrespect someone by posting horrid rumors and/or embarrassing pictures to hurt the friendships and reputation of the bullied. This is a method used by bullies to publically humiliate their victims and can commonly be done indirectly. The bully can publically post a distressing picture of the victim without "tagging" him or her to it. This will allow anyone to see it and the target not having to know the picture is being publicized.

"Impersonation" is the act of pretending to be someone else to send and post harmful material to incriminate or harm the person, friendships, and reputations. With the use of technology, the ease of accessing someone's social media profile and creating a fake, with the person's own pictures, has become an everyday occurrence. Often the bully doesn't have to create a fake profile; he or she can "hack" their victims' social media account and cause damage. Denigration and impersonation are two ways that bullies might "out" their victim. "Outing" is sharing someone's secret(s), embarrassing information, or private pictures online. This term is commonly heard in the LGBT community when someone who has not publically announced his or her sexuality is suddenly exposed as gay or lesbian. However, this term is universal when dealing with the exposure of personal information by a bully to harm or embarrass the victim. This type of exposure can be done directly or indirectly as well using deceit and manipulation. "Trickery" is the action of talking someone into revealing embarrassing information or images online. This is a method used by traditional bullies without the use of technology, usually by manipulation or blackmail. Another method used both online and offline is "exclusion." This occurs when the bullying party purposely and harshly omits someone from a group or event using rejection. Cyberbullies do this by excluding the victim from an exclusive online social group, causing the person to feel unwanted and unimportant. Online bullying takes an even more drastic progression from the traditional method of stalking to being able to stalk a victim without physically seeing or knowing the person. "Cyberstalking" is intense repetitive harassment towards someone using threats and denigration to bestow substantial fear.

EXAMPLES OF CYBERBULLYING IN THE MEDIA

Throughout advancements in technology there have been several cases in which people have been victimized by cyberbullies. There are several different ways that this is possible. In some cases bullies stalk their victims. In other cases they post hateful and rude comments and messages on social media sites and instant messaging. Cyberbullying happens everyday, but it goes unrecognized in most cases. However, there are some cases that have been brought to light by the news and social media.

Manti Te'o and Catfish

Perhaps one of the most devastating occurrences of cyberbullying is what is known as catfishing. Catfishing is the act of creating a false emotional relationship through an internet site with someone who believes that the relationship is with a real person. Most people who are considered catfish create fake profiles with real pictures that are stolen from a real person and made to look like a completely different person. In essence, an identity is stolen to create a fake relationship.

One of the most publicized times that this has happened was the instance of the Manti Te'o hoax. Manti Te'o was a football player at Notre Dame, and had begun to form a relationship with Lennay Kekua in his freshman year of college. At first it was a friendly relationship, but then it became much deeper. He began to form an emotional connection with her. There were times when he would attempt to meet her but his attempts would fail. There were also times when he would attempt to video chat but his attempts at that would also fail. This relationship went on for several months. At one point, Manti was informed that she had gotten into a terrible car accident and was left in a coma. When she was finally out of the coma, she was supposedly diagnosed with Leukemia. She was released from the hospital, and the next day Manti was informed that she had passed just hours after his grandmother. Then he was informed that the entire relationship had been a hoax. Lennay had never existed, but the pain he felt was real. He had been a part of a cruel prank, and had lost someone that he really cared about and really thought existed. His story went viral, and became a high profile case. This kind of thing happens quite frequently, but his story was in the limelight because he was well known prior to the incident. The media ridiculed him and said that he was a liar and even went as far as to spread the theory that he might have used this story to gain publicity or even to hide that he was gay.

Not only did this prank hurt Te'o, but it also hurt his family and friends. It also hurt Diane O'Meara, the face of Lennay Kekua. Tuisasosopo, who had gone to school with Diane, had stolen pictures from her facebook and even asked her to record videos, so he could send them to Manti. Diane was unaware of what Tuisasosopo was really doing with her pictures and videos as he had told her that he was using them for awareness for his ill friend. After her face was plastered across the media, she faced many challenges. People accused her of setting the hoax up as well as playing a role in the entire prank. She denies that she had anything to do with it. She was just as much a victim as Manti was. As for the perpetrator, Tuisasosopo used the scandal to test his sexual orientation. He had a crush on Manti, and used this fake profile to form a relationship with Manti. Things like this happen every day to average people. There is really no way to stop it from happening. Even setting privacy blocks on websites was not

enough for Diane O'Meara. There was also no way for Manti Te'o to know that this was all a hoax.

Richie Incognito and the Miami Dolphins

Richie Incognito was an offensive lineman for Miami Dolphins until he was released from the team in late October of 2013. His release was based on his past record of bullying other teammates, which he described as "toughening them up" (Sciullo, 2013). Jonathon Martin was a second year player for the Dolphins, until his lifestyle and the bullying from other teammates were causing him emotional distress. After an incident in the football team's cafeteria and because of the bullying from his teammates, particularly Incognito, Martin left the team. Afterwards, Martin's representative released a voicemail and other evidence of abuse from Incognito to the Dolphins. After leaving the team, Martin then began to face cyberbullying from other teammates and Incognito. Calling him a quitter and other harmful names, Martin's twitter account and phone began to receive all sorts of accusations of being a traitor to his team.

From this incident, a more thorough investigation was done on Incognito's past relationships with other teammates. His history of bullying goes back to 2002, when he was accused of bullying a walk-on offensive lineman, Jack Limbaugh. Incognito was only a freshman at the time, in Nebraska. More evidence appeared following the full investigation, where Incognito had been reported for bullying an Asian-American trainer as well. His history of abuse included harsh racial and sexual slander towards all those he bullied (Tracy, 2014). However, even after the proof of Incognito's bullying was exposed, his teammates defended him. The team blamed Martin for breaking the rules of locker room conduct by taking Incognito's jokes so personal. They viewed the text messages, voicemails, and verbal slurs as common horse-play. After the investigation was over, Incognito was taken off the non-football illness list and indefinitely released from the Miami Dolphins. Although he was released, he signed papers finalizing his retirement as a way to still receive an income and not be financially burdened.

The case between the Miami Dolphins and Richie Incognito did not lead to a tragic ending for Martin either. He was reunited with his first head coach after the Dolphins agreed to trade him for another draft pick with the San Francisco 49ers. This case opened a lot of closets, revealing cyberbullying and bullying among many professional athletics. This is only one case that shows how cyberbullying can affect adults rather than just children and adolescents.

New Jersey versus Dharun Ravi

Tyler Clementi was an 18-year-old individual who had recently graduated high school and was a freshman at Rutgers University. He was a prominent violinist and was an excellent student. The summer before his first semester at Rutgers University, Tyler Clementi told his parents that he was gay. His father was accepting and his mother was as well but was a little withdrawn. After coming out to his parents, Clementi posted on Twitter about this event and his newly found feelings. During this summer he was also assigned a roommate at the university. Both young men, Tyler Clementi and Dharun Ravi, used social media to learn a little about each other.

By visiting Clementi's Twitter page, Dharun Ravi discovered that his new roommate was gay. After reading this, he posted, "Just found out my roommate is gay." They went on as roommates with no evidence of animosity or detestation until Clementi asked to have the dorm room to himself on the night of September 19, 2010. Ravi complied with Clementi's request and left for the night, but not until he set up his webcam so that he could watch. Once Ravi left, he went to a friend's dorm room to watch what was happening in his own room. He had set up a live stream from his camera and was able to see Clementi and his date, in addition to broadcasting it to other friends. Ravi then posted on twitter, "Roommate asked for the room till midnight. I went into molly's room and turned on my webcam. I saw him making out with a dude. Yay."(Squawstar, 2012).

Clementi saw the post and reported this incident to the resident hall advisor as well as his beliefs that Ravi would again spy on him. Ravi's excuse for setting up the webcam was because he was worried about theft. The resident hall advisor showed little interest in the incident and Clementi left. Ravi posted early one day, "Anyone with iChat, I dare you to video chat me between the hours of 9:30 and 12. Yes it's happening again." Clementi then went and requested that he be assigned to a different dorm room, but nothing happened. After viewing Ravi's posts about seeing Clementi and his date engaged in romantic activities, Tyler Clementi walked to the George Washington Bridge and jumped off. Taking his own life at the age of 18, Clementi had felt humiliated and uncomfortable, because one person invaded his privacy and exposed it (O'Donnell, 2012)

Ravi was charged with 15 indictments, which included invasion of privacy and hate crimes, but not murder. He was found guilty on all counts and could have faced years in prison. However, Ravi was sentenced to 30 days in jail, 300 hours of community service, and 3 years of probation. He spent 20 days in jail before he was released. To the family of Tyler Clementi, this was far too tolerant and unjust. Since the incident, the Clementi family has created the Tyler Clementi foundation, which hopes to help teenagers and young adults against this type of bullying by promoting safe, inclusive, and respectful social environments.

WHAT SHOULD BE DONE

The result of cyberbullying has shown devastating psychological consequences to the victim. With symptoms of depression, anxiety, and even suicidal thoughts, cyberbullying prevention plans have been brought forward to help spot victims of cyberbullying as well as identify the bullies. Almost all settings, workplace and educational, have strict policies against bullying and cyberbullying. Policies that restrict people from using social media and electronics as tools to bully are fairly new, considering the advancement of technology in the past decade. Preventing cyberbullying is different than preventing traditional bullying.

Because of the rapid use of social media and other electronics, it is close to impossible to keep the bullying messages away from the victim. Second, because of the ability to release a rumor or statement on the Internet to the entire world, it is impossible to see how many people have seen it. Lastly, the ability for the bully to remain anonymous with ease makes it difficult for officials to pinpoint the bully. Educational, workplace, and most other settings have now implemented policies to intervene between bullies and their victims. However, it is usually up to the individual(s) to come forward and report the incidents. For instance, if a student posts a

humiliating video of another student off campus and after school hours, the school doesn't have the authority to fully punish the bully and must leave it up to local law enforcement to continue with the investigation.

Another problem that occurs is separating cyberbullying from just joking. This is up to the victim to decide. If the victim doesn't tell the cyberbully that their jokes are offending them, then the bully can say that he or she was just "joking". This does not include forward taunts or threats; those that are obviously causing harm cannot be passed off as joking. Cyberbullying cases are often passed off as simple joking or kids being kids, but through prevention programs and no bullying policies among schools and workplaces; it is more difficult to bully traditionally or through social media and with the use of technology. Federal and State governments have both implemented new policies to old bullying prevention methods, adjusting the way we view bullying and how we recognize victims (Jordan & Austin, 2012).

Since technology is growing more advanced every year, schools and offices have become more aware of what to look for when identifying possible victims of bullying. Almost all schools have implemented a no-bullying policy, which includes cyberbullying to a certain degree, and states have implemented laws that identify bullying as harassment (Goodno, 2011). These laws and policies help make it more difficult for bullies to succeed in victimizing others and overall find just for those that have been harmed, physically or mentally. However, with electronics and social media being around every corner, these laws and policies must consistently advance and adapt to new ways that cyberbullies impair others.

ABSTRACT

Introduction. Bullying is one of today's biggest problems in Public Health. It occurs very frequently, especially in adolescence, and action is needed to lessen its causes and alleviate its consequences. Research has shown that behavior problems usually interact with other risk and protection factors, as well as with factors of etiological development. The *objective* of this investigation was to establish a hypothetical relationship between *personal self-regulation, resilience, coping strategies* and *engagement-burnout*, which would serve as a foundation for new lines of intervention at university.

Method. A total of 253 university students participated in this research. Assessment questionnaires for *personal self-regulation, coping strategies, resilience* and *positive-negative emotionality* were completed on an anonymous, voluntary basis during class time, at different points during the 2012-2013 academic year. Correlation analyses and structural analysis were performed, using an ex post-facto design.

Results. Results showed significant association relationships between self-regulation and resilience, between resilience and type of coping strategies used to cope with stress, and between resilience and burnout-engagement.

Discussion and conclusions. Greater *personal self-regulation* is significantly associated and interdependent with a greater level of *resilient* behavior, and *resilient behavior* in turn is similarly related to more *problem-focused coping strategies*, and more *engagement behavior* in dealing with stressful situations. The results suggest a line of research for skill-training programs as a means to deal with bullying. This evidence should be applied to intervention programs, both for training in *personal self-regulation*, and for implementing *resilient behaviors* and *coping strategies* with *engagement behavior* for managing this type of stressful situation. Future investigations should explore this line of work, which has not been fully considered to date.

INTRODUCTION

Bullying is one of the major problems of Public Health. It occurs frequently and requires attention in order to mitigate its causes and consequences, especially during adolescence (Espelage & Horne, 2007). Research has shown that behavior problems are usually interrelated with other risk and protective factors, as well as with factors of etiological development. Bullying, substance abuse and the increase in a broad range of social problems all point to the need for children and adolescents to develop the skills needed for negotiation and interpersonal relationships (Swearer, Espelage & Napolitano, 2009).

Definition and Scope of the Problem

Olweus (1993) defined it as the situation where one or more students, whether bullies or victims, are repeatedly exposed to negative actions on the part of one or more of their peers. Bullying “is a process of intensification of a conflict (escalation) in which one person is in a position of inferiority and is the victim of systematic negative actions by one or more attackers. Bullying “refers neither to a conflict resulting from an accident or an isolated event, nor a conflict in which the aggressor and the victim have an equal power relationship” (Einarsen et al. 2011, p. 15). There are different types of bullying.

1. *Physical and verbal bullying.* Much research has focused on these two types of bullying, including name-calling, pushing and shoving, taking away objects and hitting. A distinction has been made between the motives for and purposes of bullying, as well as between *proactive* and *reactive* bullying.
2. *Relational bullying.* Bullying has generally been defined as behaviors intended to hurt someone else, whether by physical or non-physical means (Berkowitz, 1993). There are different types of non-physical bullying: *Relational* or *social* bullying takes many shapes and has to do with peer relationships, including hurting others through the withdrawal of relations or feelings of acceptance, friendship and inclusion in the group. Rumors and exclusion are used to maintain status between peers (Card, Stucky, Sawalani & Little, 2008). Social bullying has been related to deficient social skills and the increase of psychopathologies (Crick & Zahn-Warler, 2003). In addition, it has

been related to a lack of academic engagement, low academic achievement, conflicts with the teacher and health risk behaviors, such as use of substances (Murray-Close, Ostrov & Crick, 2007). Furthermore, exposure to relational bullying behaviors has a negative impact on the social, emotional and psychological climate of the school, with more feelings of insecurity among the students (Glew, Fan, Katon & Rivara, 2005), a decrease in classroom participation and school avoidance (Buhs, Ladd & Herald, 2006).

3. *Cyberbullying*. Technological systems are not free from relational issues. Bullying in these contexts has been referred to with such names as cyberbullying, e-bullying or digital bullying. As the use of these technologies has grown exponentially among teenagers, there has also been a rise in their misuse.

Academic and Psychological Correlates of Bullying

A recent study (Glew et al., 2005) illustrates the correlation between bullying experiences and low academic achievement. Victims of bullying report negative psychological, emotional and behavioral consequences, as well as poorer school adjustment, with greater levels of depression, avoidance, suicidal ideas and lower self-esteem, than their non-victimized peers. In addition, they report more *internalized problems*. In the long term, problems may become serious, with more *externalized problems* and more probability of psychiatric behaviors. Research that addresses the stability of *bullying* has focused on physical bullying, suggesting that it is a stable trait (Herrenkohl et al., 2009). It has also shown that *victimization* is also relatively stable during childhood (Beran, 2008).

Context of Bullying: Individual, Peer, Family and School-Related

1) *Individual characteristics*. Certain personal characteristics increase the likelihood of being bullied, such as not fitting into the group, obesity, receiving remedial classes and learning disabilities. Unlike early research (in favor of the girl students), some recent studies minimize the effect of gender on being victimized (Card et al., 2008). There is little research with regard to the role of ethnic groups or religion, but it has been observed that belonging to a minority ethnic group can be a cause of bullying.

There are individual protective factors against bullying. Empathy has a consistent, negative association with bullying, and a consistent, positive association with prosocial skills. This fact is especially important when the bully understands the emotional state of others and wishes to disturb this state. *Anger* and *hostility* have been consistent correlates of bullying, since some studies show anger to be a good predictor of bullying actions. *Impulsiveness* has also appeared to have an important role in victimization and in bullying actions (Espelaje, Bosworth & Simon, 2001). In one study with pre-adolescents, greater use of drugs and alcohol was found in those who practice bullying (Pepler et al, 2002).

2) *Characteristics of peers*. Bullying may be encouraged and sustained by certain characteristics of the peer group, especially by *attitudes* toward following group rules. There are different hypotheses, such as the homophily hypothesis, attraction theory, and dominance

theory. Prevention programs must take on systematic assessment and intervention in order to change the rules of peer interaction.

3) *Family characteristics.* With regard to the family context, research has reported that students who practice bullying have authoritarian parents who use physical punishment and show indifference toward their children (Olweus, 1995). Secondary students who were classified as bullies and bully-victims showed significant differences in terms of less social support from their parents, and there is evidence that students with affective maternal experiences showed fewer disruptive relationships and bullying behaviors.

Personal Determining Factors for Coping with Bullying: Personal Self-Regulation and Resilience

Personal Self-Regulation

Personal self-regulation refers to the capacity or ability to control our own thoughts, emotions and actions. Through self-regulation we are able to consciously control the amount that we eat, whether to act on an impulse, our task execution, obsessive thoughts, and even the extent that we allow ourselves to listen to our own emotions. We can therefore affirm that personal self-regulation is a vital process that allows people to behave adequately, carry out tasks properly, and abstain from activities that may be harmful to their own livelihood (Baumeister & Heatherton, 1996). Self-regulation is used in a number of processes including the regulation of emotions, thoughts and actions for physical or behavioral control or restraint (Baumeister, Bratslavsky, Muraven, & Tice, 1998; Vohs et al., 2008).

Different theoretical models have outlined the characteristics of this psychological construct. From a sequential approach, Kanfer (1986) proposed a model within the so-called *open-loop* conception (Bandura, 1986), where self-regulation is conceived as a self-correcting procedure when faced with discrepancies, indications of imminent danger, or conflictive motivational states that activate the system of observation. The present study adopts this conception. Miller and Brown (1991) modify postulates of the Kanfer (1986) model, providing a better explanation for changes in addictions.

If there is a deficit in any of these self-regulation processes, one's behavior regulation will suffer. Within this theoretical framework, Brown (1998) defines self-regulation as a person's ability to "plan, monitor and direct his or her behavior in changing situations" (p.62). In essence, this model adopts the self-regulation postulates of Zimmerman (2002), by defining moments of planning, control and thoughtful evaluation of one's action. Hoyle (2010) also speaks of these discrepancies and of the actions that we carry out in order to obtain our objectives and what we desire. He calls these actions self-regulation, actions that are natural and often are automatic responses of a healthy person in order to cope with the day-to-day discrepancies that are found between one's expectations or desires and one's reality.

Self-regulation as described above has been related mainly to addictive behaviors: gambling, and alcohol and drug use (Brown & Newby-Clark, 2005; Neal & Carey, 2005). This self-regulation takes the qualifier "personal" in order to differentiate it from "academic", and has been studied in both adolescents (de la Fuente, Peralta & Sánchez, 2009; de la Fuente, Trianes, Peralta & Sánchez, 2007) and university students (de la Fuente, Berbén & Martínez, 2006). *Personal self-regulation* is a construct that has been used to a greater extent in the field of health (Brown, 1998; Muraven, Collins, Morsheimer, Shiffman, & Paty, 2005; Muraven,

Collins & Nienhaus, 2002). However, after Zimmerman (1998) showed the existence of processes that are common to different domains, experts have begun to show interest in analyzing the self-regulating components that are common to different spheres of life, such as education and work.

Brown, Miller and Lawendowski (1999) constructed the Self-Regulation Questionnaire (SRQ) to measure self-regulation based on their theoretical model. Later, after performing further analyses, they developed an abbreviated version, the *Short Self-Regulation Questionnaire* (SSRQ), which was validated in a Spanish sample by Pichardo, Justicia, Berbén, de la Fuente and Martínez-Vicente (in press). The data show good fit to the structure of seventeen items grouped under four factors (goal setting-planning, perseverance, decision making and learning from mistakes). This instrument has been used mainly in connection with substance abuse, and has been subjected to an examination of its psychometric characteristics on several occasions (Carey, Neal & Colling, 2004; Neal & Carey, 2005). Its use has also been extended beyond substance abuse to address aspects such as psychological well-being, disposition to happiness (Okum, Levy, Karoly & Ruleman, 2009), depression symptoms (Kogan & Brody, 2010) and career adaptability (Creed, Fallon & Hood, 2009), and is in demand in other areas such as education (de la Fuente, Peralta, Sánchez, 2009). However, its possible role as a personal characteristic in the bullying phenomenon has not been established.

Resilience

Spencer et al. (2012) have defined *resilience* as a psychological resistance characteristic (the opposite of vulnerability), especially in extreme situations such as catastrophes and social inequality. The PVEST Model, *Phenomenological Variant of Ecological Systems Theory* (Spencer, 2008) makes several assumptions: Each person has a degree of vulnerability, based on different degrees of protection and of risk; 2) level of engagement in stressful situations refers to the support or possible changes that a person can make within his or her environment. The role of resilience in an individual's social problems, and specifically in bullying situations, has not been precisely established.

Procedural Determining Factors for Coping with Bullying: Coping Strategies

We find ourselves socially at a very complex time, when the word stress appears frequently in day to day life, and has become a familiar concept. When we speak about coping we refer to cognitive and behavioral efforts to manage stress (DeLongis, Holtzman, Puterman, & Lam, 2010). Holroyd and Lazarus (1982) define *coping* as “cognitive and behavioral efforts to master, reduce, or tolerate the internal and/or external demands that are created by the stressful transaction” (p. 843). Lazarus (1991) defines coping as “cognitive and behavioral efforts to manage specific external or internal demands (and conflicts between them) that are appraised as taxing or exceeding the resources of a person” (p. 112).

Coping strategies in the context of Educational Psychology are more related to academic stress and specifically to one of its main stressors, tests (Piemontesi & Heredia, 2009). We consider it of vital importance to examine coping strategies, since all university students must face the external stressor of tests, as well as other stressors. We must also keep in mind that university students are a very specific population, as are the ways that they deal with stress. Hence the importance of introducing this variable in the present research, as mentioned above.

Fewer studies have been carried out in this field, but relationships have been found between coping strategies and academic performance (Cohen, Ben-Zur & Rosenfeld, 2008) and student gender (de la Fuente, Cardelle-Elawar, Martínez-Vicente, Zapata & Peralta, 2013). In addition, students' levels of stress have been studied in conjunction with the coping strategies they use (Ticona, Paucar & Llerena, 2010).

Lazarus and Folkman (1986) consider one distinction to be extremely important: the difference between coping that is directed toward handling or altering the problem (*problem-focused coping*), and coping aimed at regulating the emotional response that the problem brings about (*emotion-focused coping*). The importance of the present study stems from the lack of research on coping strategies in conjunction with other variables of Educational Psychology, such as learning approaches, achievement and satisfaction with learning.

Attitudinal Determining Factors for Coping With Bullying: Engagement-Burnout Emotions

While *motivation* has been conceived as a psychological construct, *engagement* has been defined as emotional involvement that accompanies an object or experience of intense interaction. This is created by the dynamics of a situation or the immediate context, and is not very different from the concept of *situational interest* (Hidi & Anderson, 1992). *Engagement* has been conceptualized as a personal trait and as different *states of contextual interaction* (Schunk, Pintrich & Meece, 2008).

According to Shernoff (2012), *engaged students* are those who are absorbed in their scholastic, academic and learning concerns, while *non-engaged students* are bored, distant, separate from and alienated from school. Friedrichs, Blumenfeld, and Paris (2004), after observing diverse conceptualizations and measurements of this construct, conclude that *academic engagement* is a multidimensional construct that involves three dimensions: 1) *Cognitive engagement* (an investigation of learning, self-regulation); 2) *behavioral engagement* (positive behaviors, demonstrated effort); 3) *emotional engagement* (interest and not boredom). *Engagement*, as a psychological construct, arises from contributions from the Positive Psychology paradigm, in contrast to the *burnout* construct, a name for emotional fatigue or exhaustion, with loss of control that is produced in situations of ongoing stress. This construct has been studied extensively in different health- and stress-related problems, but it has not been sufficiently related to bullying.

Aims and Hypotheses

Based on the previous research, the *aim* of this investigation was to establish a hypothetical relationship between personal self-regulation and resilience (presage variables), with coping strategies (process variables), and engagement-burnout emotions (product variables), which would serve as a foundation for new lines of intervention in bullying problems at university. Consequently, our hypotheses were:

1. *Personal self-regulation* would be associated positively with *resilience* – where the former is an integral part of the latter – as well as with positive emotionality or *engagement*. It would also be associated negatively with *burnout*.

2. *Resilience* would be associated with greater use of *problem-focused strategies* and with less focus on emotions, thereby contributing to problem resolution in cases of bullying, and not only to avoidance.
3. *Resilience* would show a significant, positive association with the positive emotionality of *engagement*, and a negative association with *burnout*.
4. *Problem-focused coping* strategies would predict positive emotionality, or engagement, while *emotion-focused coping* strategies would predict negative emotionality or burnout.

METHOD

Participants

A total of 253 students from higher education participated in this research, including current students from the University of Almeria (Spain) and university graduates who were preparing for competitive exams for public employment. The current university students were pursuing degrees in general Psychology or School Psychology (*Psicopedagogía*). The mean age was 23.08 years (SD=4.4).

Instruments

1) *Personal self-regulation* was measured using the *Short Self-Regulation Questionnaire SSRQ* (Miller & Brown, 1991) in its Spanish version, the CAR (De la Fuente, 2003a). It has already been validated in Spanish samples (Pichardo et al, in press), and possesses acceptable validity and reliability values, similar to the English version with 16 items, including such factors as (1) personal goals, (2) perseverance, (3) decision making, and (4) learning from mistakes.

2) The *coping strategies* variable was measured using the *Escala de Estrategias de Coping* (EEC) [Coping Strategies Scale], in its original version (Chorot & Sandín, 1987; Sandin & Chorot, 1993, 2003). A total of 90 items are included where students respond to items on a 4-point likert-type scale ranging from 0 (never use the strategy) to 3 (always use the strategy). The scale possesses acceptable validity and reliability values. It was constructed according to theoretical-rational criteria, considering the Lazarus and Folkman questionnaire (1984) and taking coping assessment studies by Moos and Billings (1982) as a basis. The latter studies make up the theoretical framework, that is, the general dimensions of coping (appraisal-focused, problem-focused and emotion-focused coping), as well as the different categories that belong to these three dimensions. For each dimension in general, more specific subdimensions are identified. Psychometric properties are acceptable. This questionnaire is composed of 13 factors and two dimensions:

Dimension: emotion-focused coping F1. Fantasy distraction; F4. Religious support; F6. Help for action; F8. Preparing for the worst; F9. Venting and emotional isolation; F11. Resigned acceptance;

Dimension: problem-focused coping: F2. Help seeking and family counsel; F3. Actions aimed at the causes; F5. Self-instructions; F10. Positive reappraisal and firmness; F12. Communication of feelings and social support; F13. Seeking alternative reinforcement.

3) *Resilience*. Resilience was assessed using the CD-RISC Scale (Connor & Davison, 2003) in its validated Spanish version. It has adequate reliability and validity values in Spanish samples, with a five-factor structure: F1. Persistence/tenacity and strong sense of self-efficacy (TENACITY); F2. Emotional and cognitive control under pressure. (STRESS); F3. Adaptability/ability to bounce back (CHANGE); F4. Control/meaning. (CONTROL), and F5. Spiritual influence (SPIRITUAL)

4) *Engagement-Burnout*. Engagement burnout was assessed with a validated Spanish version of the *Marlach Burnout Inventory Survey-Utrecht Work Engagement Scale for Students* (Shauffeli et al., 2002). This version has shown adequate reliability and construct validity indices in this cross-cultural study.

Procedure

Information from self-reports was collected in the classroom during regular class hours from both types of students. For the university students, data on *Presage* variables (personal self-regulation, resilience, sex, age) was collected during the month of October. Later, in the month of February, students completed the scales measuring *Process* variables (coping strategies). In the months of May-June, engagement-burnout was assessed (*Product* variables).

Design and Data Analyses

The nature of this investigation, in addressing its objectives and hypotheses, adopts a non-experimental ex post-facto design. In terms of data collection, it is a survey investigation using self-reports (questionnaires and scales) and a cross-sectional strategy. Association analysis through Pearson bivariate correlations was used. Analyses were carried out to meet the proposed objectives and test hypotheses using SPSS version 21.00 for Windows. SEM analysis of structural relations was carried out using the AMOS program, v.16.

RESULTS

Personal Self-Regulation and Resilience

Total score on *personal self-regulation* was positively associated with the *Resilience* total ($r=.318, p<.001$), with high values for *tenacity* ($r=.290, p<.001$), coping with stress ($r=.262, p<.001$), adaptability to change ($r=.128, p<.01$), control ($r=.221, p<.001$) and spirituality ($r=.105, p<.05$). As for the components of self-regulation, *goals*, *perseverance* and *learning from mistakes* had significant, positive associations with tenacity (max. $r=.265, p<.001$), with coping with stress (max. $r=.299, p<.001$) and with control (max. $r=.279, p<.001$).

Personal Self-Regulation and Engagement-Burnout

Total score on personal self-regulation was positively associated with *engagement* ($r=.369$, $p<.01$), with high values for *vigor* ($r=.350$, $p<.01$), *dedication* ($r=.298$, $p<.05$) and *absorption* ($r=.299$, $p<.05$); and negatively associated with *exhaustion* ($r= -.203$, $p<.05$), as well as with lack of effectiveness ($r=-.380$, $p<.01$). As for the components of self-regulation, *perseverance* had a significant, positive association with *engagement* ($r=.363$, $p<.01$), while *goals* ($r=-.299$, $p<.05$) and *decision making* ($r=-.302$, $p<.05$) were negatively associated with exhaustion.

Resilience and coping strategies

Total *resilience* showed a significant, positive association with problem-focused coping strategies, but not with emotion-focused strategies. The *spirituality* component was associated with use of emotion-focused strategies. The *change* and *control* components were associated with the use of problem-focused strategies. Specifically, the components of *personal competence-tenacity* and *context of stress* were associated with the use of self-instructions, help-seeking, positive reappraisal and firmness, and seeking alternative reinforcement, and negatively associated with emotional venting and resigned acceptance. The *spirituality* component was positively associated with fantasy distraction, religious support and resigned acceptance. Inferential analyses confirmed these differences between the high-medium-low groups in resilience. See Table 1.

Table 1. Relations between coping strategies and resilience

	Tenacity	Stress	Change	Control	Spirituality	Total
F1. Fantasy distraction	.050	.159**	.015	-.044	.190**	.129*
F4. Religious support	.034	.073	-.080	-.032	.383**	.158**
F6. Help for taking action	.136*	.084	.030	.121*	.075	.128*
F7. Reduction of anxiety and avoidance	-.052	-.013	-.066	-.055	.059	.001
F8. Preparing for the worst	.033	.027	.013	-.090	.034	-.013
F9. Emotional venting and isolation	-.153**	-.095	-.244**	-.255**	-.031	-.225**
F11. Resigned acceptance	-.089	.019	-.175**	-.249**	.126*	-.099

Note. * $p<.05$; ** $p<.01$.

Resilience and Engagement-Burnout

Total score in *resilience* was negatively associated with exhaustion and lack of effectiveness (burnout), and positively associated with vigor (engagement). The most clearly related component of resilience was control, with a significant positive association with vigor, dedication and absorption, and a negative association with exhaustion, cynicism and lack of

effectiveness. Similarly, competence-tenacity was positively associated with vigor and negatively with lack of effectiveness.

Table 2. Relations between resilience and engagement-burnout

	Tenacity	Stress	Change	Control	Spirituality	Total
Exhaustion	-.250	.093	.092	-.318*	-.337**	-.363**
Cynicism	-.193	.057	.034	-.341*	-.120	-.244
Lack of effectiveness	-.141**	-.039	-.010	-.403**	-.081	-.346*
<i>Burnout total</i>	-.313*	.055	.23	-.423**	-.248	-.379**
Vigor	.458**	.202	.097	.486**	-.135	.317*
Dedication	.225	-.006	-.067	.489**	.031	.026
Absorption	.197	.235	.049	.296*	-.160	.189
<i>Engagement total</i>	.316*	.156	.019	.482**	-.124	.267

Note.* $p < .05$; ** $p < .01$.

Coping Strategies and Engagement-Burnout

Total score for *coping strategies* was positively associated with *burnout* ($r = .409, p < .01$), but not with *engagement*. In complementary fashion, *emotion-focused* and *problem-focused* coping strategies were positively associated with *burnout* ($r = .358, p < .01$; $r = .368, p < .01$, respectively).

More specifically, some coping strategies were negatively associated with *engagement*, such as *resigned acceptance* ($r = -.419, p < .01$), and *emotional venting* ($r = -.457, p < .001$). However, there were numerous specific associations between *emotion-focused* coping strategies and *burnout*, such as *fantasy distraction* ($r = .300, p < .05$), *preparing for the worst* ($r = .536, p < .001$), *emotional venting* ($r = .495, p < .001$) and *resigned acceptance* ($r = .311, p < .05$). There was also a positive association between *problem-focused* strategies and *burnout*, referring to actions directed at the causes ($r = .352, p < .01$).

Building a Model of Relations

SEM analyses showed a significant relations model ($\text{Chi-square} = 25,085$; Degrees of freedom = 4; $p < .001$) with acceptable indices ($NFI = .988$; $RFI = .968$; $IFI = .983$; $CFI = .994$; $RMSEA = .05$). This model reveals how *personal self-regulation* (SRQABREV) positively predicts *resilience* (CDRISCTOTAL), as well as *problem-focused strategies* (AFRONT-PROBLEMA) and negatively predicts *emotion-focused strategies* (AFRONT-EMOCION).

At the same time, the model shows how *burnout* is predicted positively by *emotion-focused coping* (AFRONT-EMOCION) and negatively by *problem-focused coping* (AFRONT-PROBLEMA), while *engagement* is predicted positively by *resilience* (CDRISCTOTAL) and by *problem-focused coping*. See Figure 1.

Figure 1. Structural model of relationships between self-regulation, resilience, coping strategies and engagement-burnout.

DISCUSSION

Prior research on *personal self-regulation* has provided evidence of its association with other constructs, such as learning approaches, coping strategies (de la Fuente & Cardelle-Elawar, 2011) and self-regulated learning (Zapata, 2013). Results from the present research are complementary, establishing a consistent connection between these motivational presage variables (personal regulation and resilience), process variables (coping strategies) and product variables (positive vs. negative emotionality), based on the 3P Model by Biggs (2001). In overall terms, they provide empirical support for the hypothesized relationships, helping us understand the role played by the presage variables in the process variables, and the role of both presage and process variables in positive vs. negative emotionality while learning at university. This would mean that, according to one's level of personal self-regulation and resilience, different coping strategies would be used, and these would ultimately produce an experience of psychological well-being and positive emotionality, or alternatively, some level of burnout or negative emotionality.

The results are important because they show how each component of *resilience* is differentially associated with a specific use of *coping strategies*. The common denominator of the resilience components is their positive association with strategies of *self-instructions*, *positive reappraisal* and *firmness*, and their negative association with *emotional venting* and *isolation*. There are implications for theoretical relationships between the constructs, as well as for psychological intervention with university students in stressful contexts, particularly in bullying situations.

Prior research has shown the relationship between emotions and attention, memory and problem-solving processes (Clore & Huntsinger, 2009). The direct effect of emotions on performance, especially in the case of test anxiety, has also been evaluated. The cognitive-motivational model by Pekrun (2006, 2009) offers evidence for this relationship, according to the different proposed categories of emotions. Traditionally, *positive emotions* have been considered maladaptive, because they would provoke unrealistic assessments of the situation, for example, about the likelihood of failure. However, a *positive emotional state* has been found

to act as an undergirding for activation of positive emotions that lead to engagement in academic performance. For example, a positive correlation has been found between enjoyment of learning and performance on achievement tests (Pekrun, 1992), as well as between positive emotions and students' engagement and achievement (Linnenbrik, 2007).

Additionally, the use of *emotion-focused* strategies for coping with stress is associated with negative emotionality or *burnout*, while use of problem-focused strategies is not. In short, these results reconfirm the need to study *positive emotionality* (engagement) vs. *negative emotionality* (burnout) as an essential element that interacts with motivational and cognitive processes in stressful situations.

CONCLUSION, LIMITATIONS AND IMPLICATIONS

The evidence offered here presents psychological mechanisms that are of interest in the study of bullying, but have not been sufficiently examined to date. If personal variables are indeed mediators of stress and stressful experiences, students' level of *personal self-regulation* and of *resilience* when exposed to bullying situations ought to be analyzed – and if appropriate, developed through training -- since these levels predict different use of coping strategies and result in different emotionality. Also, further research and therapeutic interest should be taken for the adjustment of *coping strategies* used in bullying situations. These coping strategies can prove to be essential tools or skills for managing these situations, for maintaining an adequate state of mental health, as has been seen in prior evidence (Hauge, Skogstad, & Einarsen, 2007). Finally, the emotional state of *engagement* or *burnout* can be considered an important correlate for evaluating the psychological impact that bullying may be making on academic achievement.

Therefore, despite the *limitations* of this investigation, with respect to the number of participants and the representativeness of our sample, the results found here alert us to the importance of evaluating levels of personal self-regulation, coping strategies, resilience and engagement-burnout that may be present in cases of bullying.

The *implications* of these results also refer to the importance these variables in understanding the individual characteristics of university students, and for taking steps to specifically train skills for managing academic stress in association with bullying or other stressful personal interactions (Giorgi, 2010; Giorgi et al, 2013). Specifically, these results are important because training in *resilience and coping strategies* can help university students become better adapted in stressful contexts and use more problem-focused strategies. It is a fact that the bullying phenomenon is a health problem, but this fact is mediated by psychological tools available to the person subjected to a bullying situation, thus increasing his or her capacity for taking action (Hoel, Faragher, & Cooper, 2004).

Chapter 46

FROM BULLYING TO PANDEMY OF TERRORISM: SYNERGETIC BIO-PSYCHO-SOCIO-SPIRITUAL METODOLOGY OF MENTAL HEALTH PROTECTION

Pavel Ivanovich Sidorov*

Mental Medicine Institute, Northern State Medical University, Arkhangelsk, Russia

ABSTRACT

The chapter examines special developmental features of the terrorist demoralization syndrome; it discerns terrorism in the classification of destructive social epidemics highlights mechanisms of manipulations with human consciousness in extremist organizations and formulates the characteristics of mental paradigm of national security. It also offers a synergetic bio-psycho-socio-spiritual system for preventive and correctional activities based on the mental medicine methodology.

Keywords: Mental terrorism, syndrome of terrorist demoralization, forms of terrorism, mechanisms of manipulations, spiritual immunity, synergy of defense, mental paradigm of national security

The pandemic of terrorism undermines civilizational fundamentals of the contemporary world. Fear and anxiety, that deform social consciousness, are becoming an everyday reality. Many countries have developed and implemented special technologies to provide special psychological and psychiatric help in case of emergency, disaster, terror, or violence. However, the questions of efficient resource provisions for the early and systematic prevention of destructive social epidemics still remain unsolved.

The chapter aims to present a conceptual and methodological explanation of terrorism and its forms, demonstrate its place in the classification of destructive social epidemics, single out mechanisms of manipulation with human conciseness in extremist organizations, show

* Corresponding Author's Email: pavelsidorov13@gmail.com.

characteristics of the mental paradigm of national security, establish the synergy of effective defense in frames of the mental medicine methods.

1. SYNERGETIC BIO-PSYCHO-SOCIO-SPIRITUAL METODOLOGY

1.1. Mental Health Synergetics

Mentality is a worldview that is formed throughout upbringing, education, and life experience in a specific cultural environment. Mentality (from Late Latin *mentalis* "of the mind," from Latin *mens* "mind,") describes notions (like *mind* in English) that have no exact equivalent in Russian. Further research will help to outline scientifically all the main definitions in mental ecology and mental medicine.

"The world health report 2001 - Mental Health: New Understanding, New Hope" (2001) by WHO reveals the decision to support scientific research that would aid a better understanding of the nature of mental health disorders and help to develop effective prevention methods.

Mental health is a state of well-being in which every individual realizes his or her own potential, can cope with the normal stresses of life, can work productively and fruitfully, and is able to make a contribution to her or his community (WHO, 2001). Most importantly, apart from the classic bio-psycho-social trinity this definition includes moral elements of self-fulfilment, resistance to stress, and productive work that are impossible without business communication ethics. The civil and political element in the appeal to "to make a contribution to her or his community" looks even more pretentious.

Mental ecology is a section of human ecology that studies connections in the "environment - society - individual" system alongside factors and resources of mental health.

Using the "Evaluation of health ecology" method we [33] quantified the effects of lifestyle (25%), environment (21%), mentality (20%), healthcare (18%), and genetics (16%) on health. Unlike the four groups of factors determined by the WHO (1992), mentality is categorised separately in our research as it is to a significant extent a behavioural expression of lifestyle (table 1).

The idiosyncrasies of the mental ecology mission lie in its interactive support for civilizational trends (picture 1). Mental health integrates the potential of moral, spiritual, psychiatric, somatic, and social health and is a constructively creative resource of the public consciousness and public health of a nation. The mental ecology mission substantially compliments the basic definition of psychotherapy as an interactive process of psychologically assembling the past, present, and future of a person, a family, a group, and society as a whole in order to achieve a set target [21]. Within synergetic methodology, a concise definition of psychotherapy as a science about adaptive management of mentality of individual and collective consciousness may be presented. Mentality is the matrix of psychotherapeutic influence in the consciousness of the client and patient, predetermining his or her lifestyle and trajectory of his or her destiny.

Picture 1. Mission of mental ecology in interactive provision of civilizational trends.

Sidorov P.I., Novikova I.A. (2008)	25	21	16	18	20

Devaluation of the moral-spiritual paradigm of development became a deep-seated cause of the global crisis and many of the problems in Russian society. Russia has essentially lost its official ideology and its society has lost its spiritual and moral ideals. “More modern” ideals replaced traditional upbringing and education:

- *christian virtues* – general humanitarian values;
- *teaching respect of the elderly and joint labour* – development of a creative egoistic personality;
- *virtue, abstinence, self-restriction* – total permissiveness and satisfaction of personal needs;
- *love and self-sacrifice* – pragmatic self-affirmation psychology;
- *interest in the culture of the motherland* – exceptional interest in foreign languages and foreign traditions.

All of this lead to growing dehumanisation and loss of ethics in the public consciousness, exposing the ineffectiveness of the pseudo-humanistic utopia connected to the idealisation of material values and self-regulating market economy. It is the main argument behind the "Concept for moral-spiritual development and character education of a Russian citizen" published by the Russian Federation Ministry of Education and Science in 2009.

Moral-spiritual education lies in forming:

- *moral feelings* - conscience, duty, faith, responsibility;
- *a moral portrait* - patience, mercy, humility;
- *a moral position* - ability to distinguish good from evil, to express selfless love, readiness to overcome life's difficulties;
- *moral behaviour* - readiness to serve the people and the motherland, obedience, good will.

A polymodal mentality is the target for (or matrix of) moral-spiritual training, education, and psychological and psychotherapeutic influence in the individual and public consciousness. To measure, figuratively speaking, the strength of personality and its potential we [33] developed and patented the "Mental ecology of a personality system" that provides for evaluation of the psycho-, socio-, somato-, and animogenesis of an individual or a group in a screening regime.

Anima, animus (Latin *anima* -soul, *animus* -spirit) are terms that in Ancient Greek culture express the phenomenon of the psyche, act as stages of the evolution of spiritual understanding: anima (soul) is inseparable from its bodily carrier, while animus (spirit) has an autonomous status.

Animogenesis is the term that integrates understanding of soul and spirit and signifies the central quarter in the three-dimensional bio-psycho-social model of mental health's ontogenetic development, filling it with bio-psycho-social-spiritual contents [32]. The major difference between animogenesis and psychogenesis is in unlocking of the content of polymodal mentality.

Synergetics is the new methodological instrument for examining the mental ecology of a person; it is an interdisciplinary science that studies formation and self-organisation. Hermann Haken coined the term "synergetics". It studies systems that consist of multiple parts, components or subsystems that interact in a complex manner.

The main principles of synergetics are its non-linearity, instability, openness, dynamic hierarchy and its observability. Synergetic methodology is based on an integrative approach to studying thermodynamically open dissipative structures far from equilibrium [2].

Dissipative structures are discretionary self-organising systems that dissipate energy, distinguished by their spiral formation in multidimensional space, its trajectory and a stable amplitude have a multifactorial quality and are predetermined by a combination of forces from varying directions and by factors relating to differing bifurcation points.

Dissipative structures form and exist in society and in the biosphere and are intermittently going through self-organisation, following their internal formation logic, they become more complex and degrade throughout their existence.

A strange attractor is an important concept in synergetics – an object in the phase space that almost all the trajectories aim for and upon which they are unstable. An *attractor* is a *fractal* (from

Latin *fractus* - fragmented) characterized by its fractional size and is a region in which trajectories disperse in some directions and attract in others.

A *fractal* is a self-similar figure made up of parts that are each similar to the whole and has nontrivial structure in all scales.

Fractal dynamics is the transformation of a quantum system from one condition to another via bifurcation, bypassing which, a dissipative structure starts aiming for a new attractor and a new structure, which in clinical psychiatry equates to the development of psychiatric disorders or recovery - depending on which of the attractors (leading to progression or remission of a mental illness) turns out to be more relevant.

Synergetics views the human body as a complex open system with non-linear processes. Its behaviour cannot be called determinate. The change of the system does not follow linear laws because of presence of internal fluctuations [28, 34], that change trajectory of development

When accumulating a large number of fluctuations, exaltation of the system towards internal or external influences grows to such an extent that those variables whose changes have not caused any significant influence on the system, start to affect change. Such points that the system passes (bifurcation points) make it possible to use the mechanism of a local increase in small fluctuations, which will enable change to the behaviour and the trajectory of the system's development in the right direction (picture 2).

Picture 2. Fractal trajectory of conditions' (illnesses) development and defence mechanisms.

The term developmental “trajectory” of a condition or illness is often used in modern foreign and Russian literature [3]. However, its use by Russian Academy of Medical Sciences member A.B. Smulevich [38] regarding “problems of personality disorder trajectory in the field of minor psychiatry” met reprimands from reviewers because it was deemed a “beautiful” term. From our point of view, the term “trajectory” is completely justified and is borrowed from the synergetic methodology for describing development in multidimensional (at least three-dimensional) space, when traditional “flat dynamics” become incapable of describing the multi-modal relationships and scenarios with multiple options of development within modern evidence-based medicine.

The synergetic concept of ontogenesis that we developed presupposes interplay of equal factors:

- *somatic health* that forms as a result of biogenesis;
- *psychic health* that appears during psychogenesis;
- *social health* that develops in the sociogenesis process.
- *moral-spiritual health* that forms during animogenesis.

The sum of the separate parts of these factors for a certain population provides an estimate of the level of its somatic, mental, social, and moral-spiritual functioning, and uniting these results helps to conduct systematic monitoring of the level of public health and public consciousness of the population under study.

Psycho-somato-social and moral-spiritual health of an individual (and public health) are impossible to imagine in isolation – independent to the effect of external factors, which in turn transform as a result of various influences on them from individuals, influencing the environment. These relationships result in a formation of a complex, nonlinear, unstable, open, self-organising system of a dissipative type that conducts energy exchange and is defined in its development by influence of multidirectional forces.

The synergetic approach can be visualised (picture 3) through the main plains (vectors) of the bio-psycho-social model of ontogenesis: somato-, psycho-, and sociogenesis. Somatogenesis presupposes the development of systems and functions of the organism; psychogenesis is the development of psychic functions; sociogenesis is the development of social roles and relationships. The central part of the intersection and integration of the three vectors forms the fourth and the main aspect – the moral-spiritual aspect of animogenesis, the core of which is a polymodal mentality. The model promotes an interdisciplinary and integrated approach to complex and complicated cause and effect relationships. The synergetic model is multidimensional and nonlinear, unstable and open. The developmental trajectories of the condition or the illness are set and corrected at bifurcation points, achieving spiral-like qualities and multiple possibilities. Nonlinear discretion and fractality replace linear and nosocentric dynamics.

The main planes of ontogenesis penetrate each other, forming transit zones and a central zone that contains consciousness, an integral part of mental health, the highest level of self-regulation and reflection of reality that accumulates moral-spiritual potential (picture 4). In the dynamics of ontogenesis the amplitude and rhythm of the main aspects diminish and by the time they fade the person's soul and consciousness become the last relevant factors [32,34].

According to the synergetic concept the development of any disorder has non-linear dynamics, the trajectory of which includes the following fractals: predisposition (family disontogenesis); latent (diathesis); initial (functional disorders); clinical picture; chronicity (forms and types of progress of the illness); outcome. In clinical medicine, a fractal is both progress and condition, uniting temporal and qualitative characteristics of the system and organism.

Synergetic methodology permits the systematic and successive integration of the whole variety of factors and resources of mental ecology in order to promote an optimal level of national health.

Picture 3. Bio-psycho-socio-spiritual model of ontogenesis.

Picture 4. Age dynamics of bio-psycho-socio-spiritual assimilation.

1.2. System Crisis of Psychiatry and Alternative Mental Medicine

The urgency of the problem of the scientific and methodological system crisis in psychiatry, that found itself on the verge of exhausting habitual concepts, often becomes a subject of discussion for experts that propose changing paradigms in psychiatry [28,33] as it appears to be a particular example of a more common difficulty faced by many modern sciences that have reached the end of another cycle of civilisation. The interdisciplinary nature of psychiatry and even more so that of psychotherapy determine the interest of various disciplines in this problem: natural sciences, humanities, technical sciences. It makes the synergetic approach all the more relevant.

Modern system problems in psychiatry are illustrated by the ICD-10 that displays eclecticism, lack of unified stylistic and ideological concepts, and a deficit of new ideas, whereas old concepts no longer measure up to the challenges of the times. These circumstances augmented the contradictory tendencies of modern psychiatry: “globalisation of approaches... and classification criteria” and “the increasing informational excessiveness of various data” [17] that divided psychiatry into a “psychiatry of facts” based on diagnostic standards and a “psychiatry of values” that individualises the approach to the patient [5].

The interdisciplinary quality of psychiatry was engendered by its interaction with other sciences leading to its unique integrity. However, in the ICD-10 the psychiatry’s interdisciplinary nature and integrity look like a mechanical union of ideas and different styles, which are often contradictory. Because of this, the problem of terminology became more relevant, highlighting on the one hand the limits of some classical terms, and on the other hand – the artificiality of new definitions. The mechanical and eclectic unity of the two approaches determined the system crisis of the ICD-10 that, along with obvious “successes” contains definitions that seem to be “multiplying the essence without need” [18]

It is notable that countries using the DSM IV diagnostic system, with all of its shortcomings, did not challenge tradition in the face of changing psychiatric treatments and their ethical and legal aspects, by adjusting to the latest ICD, which thus cannot be considered truly “international”.

The solution may lie only in establishing new synergetic methodology.

Synergetics permits us to examine mental health and mental illnesses within a single methodology. The same group of professional psychotherapists, psychiatrists, clinical psychologists, and social workers is using the same technologies and is working on both strengthening mental health of clients (who have difficulties in adapting in the absence of a diagnosis) and treating the mental health of the patients. As such mental medicine is built on an interdisciplinary synergetic methodology which unites nosocentric clinical psychiatry and health centric preventive mental health care.

Mental medicine is a science that studies etiopathogenesis and diagnostics along with the clinical picture and treatment of mental disorders, bio-psycho-socio-spiritual resources of personality and societal development, strategies and mechanisms of adaptation and professiogenesis based on a single synergetic methodology. This wording includes the classical definition of psychiatry in all the modes, specified in the mental health definition by WHO (2001), which are the priorities of mental preventology.

Mental preventology is a section of general preventive medicine, a science that studies methods of achieving and maintaining the optimum level of mental health, psycho-hygiene and psycho-prophylactics on a systematic and interdisciplinary synergetic basis.

The main tasks are combining the classical psychiatry's sphere of use with the field of interest of *mental medicine* that apart from mental illnesses studies bio-psycho-socio-spiritual resources of personality development, mechanisms of socialisation and adaptive professiogenesis, and the search for a new health-centric concept that widens the possibilities for de-stigmatisation and the work of experts in donosologic field.

In light of the aforementioned thoughts it seems relevant to compare and combine classical clinical psychiatry and mental preventology against the most important criteria of their content - direction and nature of functioning (table 2) within unified mental medicine.

Table 2. Mental medicine as a unified theory of improving mental health and treatment of mental illnesses

Criteria	Mental medicine	
	Clinical psychiatry	Mental preventology
Concept	Nosocentricity	Health-centricity
Strategy	Illness treatment	Prevention of pathology
Aim	Return of mental health	Raising quality of life
Task	Removing symptoms	Preserving functions
Object	Ill person	Healthy person
Focus	Psychiatric disorder	Normal function
Technologies	Treatment, rehabilitation	Preservation, optimisation
Priorities	Clinical	Holistic
Relationships	Paternalism	Partnership
Process	Hospitalisation	Socialisation
Dynamics	Linear	Multidimensional
Ethics	Stigmatisation	De-stigmatisation

This table permits us to compare the direction of mental preventology and clinical psychiatry, outlining their mutual compatibility when solving tasks in strengthening the mental health of the nation. Integration in mental medicine of the traditional psychiatric nosocentricity with the growing health-centric trend of improving mental health became possible via synergetic methodology and interdisciplinary teamwork. This information casts doubt on the concept of viewing the psychiatric disorder as the main and only aim and task of psychiatry. In today's context, diagnostics, treatment, and prophylactics of psychopathology have become a tactical fragment of the common strategy and direction of mental medicine towards preserving and optimising a person's mental health and increasing his or her quality of life. Mental medicine becomes a unified science pertaining to mental health and mental illnesses.

Thus, the more intensive development and research of branches of medicine, both already existing and those that have not been fully formed yet, is a natural and relevant task of modern science – not only from a scientific determinism point of view, but also from the point of view of other methodological approaches, one of them being synergetics as the base for organisationally functional interdisciplinarity, capable of forming a new paradigm of mental medicine. Projecting it on the traditional field of classical psychiatry widens the area of use for specialist knowledge, directing it at situations that do not have a clinical interpretation yet. It

demands perfecting of mental health's systematic monitoring technologies that can compliment and transform traditional clinical examination; formalising the prophylactic monitoring activity of specialists (with the appearance of specialities like "preventive medicine", "monitoring and strengthening health"); forming strategies for work on nosological field, screening mental health factors and resources; multiple potentials of trajectories of correctional prophylactic and treatment rehabilitation routes; evaluating the quality of life and social functioning, which in the end secures better results in improving the mental health of the population.

1.3. Anti-Psychiatry

Philosophical discrepancies of the mid-20th century lead to the appearance in 1960s of a movement called *anti-psychiatry* within classical psychiatry that chose existentialism and socially critical philosophy as its foundations. World Psychiatric Association President Mario May (2008) said the following about anti-psychiatry: "Anti-psychiatry is a reality in some countries. Our profession is unique in that it can create its own antibodies."

The period of decline of empires in the post-war era generated anti-system leanings in many spheres of human life. The traditional system of classical psychiatry was subjected to revisionist attempts from its opponents. Supporters of anti-psychiatry were aiming to "discover the truth hidden amongst the drivel," and in the process almost doubting the status of classical psychiatry itself as a medical science, protesting against its claims to qualifying people as mentally ill.

Anti-psychiatrists Ronald Laing, David Cooper, Thomas Szasz and others thought that the decision not to treat patients was right and that their individual and social needs, including those expressed in psychotic motives, had to be satisfied: "Instead of psychiatric hospitals, these processing plants, we need places where people who went further than psychiatrists in their wanderings and consider themselves mentally healthy would have a possibility to go even further in internal time and space and return from there"[19]. Or, as clinical practice demonstrates, never come back.

American sociologist Erving Goffman highlighted the negative sides of *psychiatric total institutions*. In Italy Franco Basaglia, the initiator of de-institutionalisation of psychiatric hospitals became the leader of the anti-psychiatry movement. In the Netherlands Jan Foudraine lead the student movement targeted against professional authority in psychiatric hospitals. Classical psychiatry was accused of having discriminating procedures within its regulations. A movement appeared for banishing psychiatric intervention from the framework of a hospital structure that for almost two hundred years had been seen as treating psychiatric patients in a space isolated from society. In 1965 David Cooper, Ronald Laing and others created the Philadelphia association, aimed at "changing the perception of *mental health and illness of the soul*" [1].

Anti-psychiatry expressed fundamental criticism of the following:

- a) illegal use of medical categories and methods regarding social and psychiatric phenomena;
- b) conventional nature of nosologic categories in classical psychiatry, their highly provisional nature, dubious medical status;

- c) not enough theoretical and clinical reasoning for distribution of these categories into rubrics in classifications;
- d) toxicity and side effects of psychotropic medicine;
- e) lack of a clearly and legally defined standard of psychiatric norm;
- f) use of non-voluntary treatment;
- g) ignoring other approaches to the problem of psychiatric disorders;
- h) compromising connections of classic psychiatry with pharmaceutical companies;
- i) cruel treatment and tight control regarding the mentally ill.

Anti-psychiatry brought to the fore the following problems:

- a) existential factors for psychiatric disorders;
- b) pathological status of psychiatric disorders
- c) place of the mentally ill in society;
- d) institutionalisation/ de-institutionalisation of the mentally ill;
- e) psychiatric disorders treatment methods;
- f) personality suppression and functioning of the institutions of authority;
- g) peculiarities of inter-personal interaction;
- h) unconscious mechanisms of society's functioning;
- i) human rights protection for people with mental illnesses.

Not one of the pioneers of anti-psychiatry developed a complete theoretical system: Laing and Cooper worked with phenomenological and existential concepts based on the theory of pathology of communication inside the family; Basaglia was concerned with politics, ideology and revolutionary social reforms; Szasz's views formed under the influence of Ludwig Binswanger and Freudianism. However, the anti-psychiatry movement influenced classical psychiatry, the nature of work by its institutions, and the quality of help for the mentally ill. Anti-psychiatry brought to light some contradictions of classical psychiatry – its conceptual and philosophic disagreement; known diagnostic arbitrariness that depends on priorities of regional schools and philosophical preferences.

Thanks to the anti-psychiatry movement, starting from the 1960s, new methods and forms of working with the mentally ill became more popular. Therapeutic communities (soterias) appeared and became popular again, but they were a modification of a method used by classical psychiatry in the 19th century (housing patients in peasant families for their full social rehabilitation and labour therapy like in the Belgian town Geel and a number of other European locations); stricter laws were passed that limited the use of non-humane methods of treatment and the regulation of non-voluntary hospitalisation; a more humane view of the mentally ill appeared; social and psychological methods became more common in their treatment and rehabilitation. Perceptions of ethical norms in classical psychiatry formed. The monopoly of the biological approach to psychiatry was broken; psycho-social approaches appeared and became more active.

Anti-psychiatry became the *antithesis* to the *thesis* of classical psychiatry, criticising its important concepts, achievements and theories, doubting its practical implementation and viability. Anti-psychiatry attacked the foundation of nosology and epistemology of classical psychiatry, criticised its lack of satisfactory criteria for diagnostics and the objectivity of its methods; doubted the very medical model of a mental illness accepted by the classical

psychiatry, considering the nosological classification arbitrary; criticised methods of therapy (“pharmacotherapy is chains locked from the inside”) and prophylactics that did not take into account social conditions; put the psychosocial aspect of the problem instead of the biological one to the foreground, treating psychotherapy as social manipulation and control; protested against obligatory hospitalisation, considering it a measure of segregating the mentally ill bereft of their human rights.

The philosophical ideology of anti-psychiatry was also eclectic and cumulative, combining the philosophical concepts of the sentimental humanism of Jean-Jacques Rousseau, existentialism of Jean-Paul Sartre, and anarchism of Peter Kropotkin. Student riots in Paris in 1968 do not look coincidental in this context: readers of Sartre were prisoners of romantically viewed anarchism and Trotskyism. It was the first example of mental design and strategies, technologies and mechanisms of the future artificial “colour revolutions.”

The difference between the authorities’ thoughts on the forms of realising the ψ -function and peculiarities of its social use were expressed through psychiatric hospitals and the mentally ill in socialist and capitalist countries. Inside the socialist system, the ψ -function came down to isolating this category of people in conditions where it was easy to conduct monitoring of this cohort. It is the *totalitarian* option of ψ -function implementation. Capitalist socio-economic formation featured the *liberal* option, declaring human rights a priority and regulating psychiatric activity with this point of view in mind.

There was an explosion of popularity and the network distribution of such methods of psycho-correction and psychotherapy as group sessions, family psychotherapy, training, role games, and behaviour modification among others. All of this became the prologue to the modern *Era of Psychotherapy*. Psychotherapy, having achieved the revolutionary breakthrough to the medical nosological field, radically changed the focus of the ψ -mission of the state and society from mental illnesses to mental health. This secured dynamic development of the whole complex of neurosciences and sped up the development of social psychiatry and narcology, leading to the birth in the last decade of mental ecology and mental medicine.

1.4. System Synthesis of Mental Medicine

If before the 20th century it was possible to talk about long-term paradigms in philosophy and science (particularly in classical psychiatry), then now various concepts of philosophical directions that exist simultaneously form a contradictory ontology and a perception of the worldview as unstable.

The world is losing stability and steadiness at the speed of a gallop and it is important to note that this is not simply the perception of “shadows of scientific illusions”. Terrorist attacks by suicide-bombers and online hacker attacks easily explode the global public consciousness, demanding principally new approaches to protecting the mental resources of the civilisation. Psychiatric fences and bars in the global and open world became totally anachronistic. Humanity as a whole and each one of us individually are so defenceless that the very realisation of this fact creates ground for social stress disorders.

Acceptance that the former canons of scientific world study turned insolvent became a common topic of polemic statements. Urgent desire for defenceless integration of classification systems in classical psychiatry is today accompanied by “the known futility of the announced methodological approach; its lack of theory; change from nosological to syndrome level of

clinical evaluations; bulkiness; inability to reflect cultural variety even when using the descriptive method, and eclecticism because of a lack of theoretical principle” [24].

Materialistic science and philosophy fully humiliate the person and the truth. Almost all empirical theories of the 19th and 20th centuries were refuted by the verdict of history as strained and pretentious exhibits of vain erudition. Despite the significant number of historical, statistical, pseudo-experimental, clinical and other data, not a single unified theory was created. At best, they only restored in a vulgar and more primitive form the generalisations of the previous generations [40].

This problem was formulated by Carl Gustav Jung in relation to classical psychiatry and psychotherapy [11]: “Modern medicine can no longer understand the psyche as part of the body and is thus considering the so-called *psychic factor* more.” “Practical loss of empiricism of modern culture is revealed in our growing inability to control humanity and the course of social and cultural processes” [40]. However, it is psychiatry that is the slowest in leaving behind the empirical period of scientific development.

In the context of a globally permanent and paroxysmally progressive crisis that fundamentally relates to the mental paradigm, modern possibilities for perfecting classical psychiatry and anti-psychiatry have almost been exhausted. “We are, seemingly, at the dusk of an era” [20]. But this “...imaginary dying agony is nothing else but sharp pain from the birth of a new form of culture, labour pains, accompanying new creative forces” [40], “a reassuring sign of possible deeper changes of the spiritual disposition” [13].

“The 21st century will become the century of returning to continuity, to all-round understanding of common problems. The key will be technologies of a certain system integration, *system synthesis*” [22], because “the main thing in the study of the living phenomena are not the elements that do not matter by themselves and do not exist, but something else – *synthesis, form, idea*” [14]. “Gradually the understanding that there is *one* humankind with *one* psyche is born and developed ... would also do away with the awkward hypothesis of psychophysical parallelism and afford us an opportunity to construct a new world model closer to the idea of the *unus mundus*” [10]

The crisis of classical sciences in the 20th century generated the use in scientific methodology of *various* interpretative and methodological systems, which lead to the understanding that it is necessary to utilise the *principle of complementarity*. “Being can only be described in part, as the other part remains at any given time unrecognised and unlimited. Life processes cannot be explained based on just the causality principle” [12].

Contradiction unites into a whole the battle and the unity of opposites, and *unity* mutually supposes and *battle* mutually exclude opposite sides. The battle of the thesis of classical psychiatry and the antithesis of anti-psychiatry brought these concepts to unipolar renditions in which both failures and achievements of these areas were subject to relativism from the opposing side. However, the thesis of classical psychiatry that was replaced by the antithesis of anti-psychiatry created conditions both for formation through the complementarity principle of a constructive *synthesis* of these contradicting concepts in mental medicine, promising a qualitatively new level of understanding and interpretation of mental health problems and mental illnesses (table 3).

Internal contradictions of the thesis and antithesis are removed by the synthesis of former ideas, capable of using new philosophical *ideology of synergetics*, called exactly “system synthesis,” “synthesis with the developed analysis” (which shows a meaningful combination

of former methodological priorities and achievements) as a base for forming a new scientific discipline – *mental medicine*.

Synergetics that uses a complex approach, and has among its most important systematic concepts the complementarity principle, can creatively unite the achievements of classical psychiatry and anti-psychiatry, evading their shortcomings that first of all appear in their methodological relativism that denies the ideological priorities of the opposing side. The appearance of a new holistic philosophy inevitably generates new synthetic methodology, capable of retrieving the practical psychiatric science from the dead end of today's contradictory and irreconcilable concepts: theory will inspire practice. Elements of new practical trends are noticeable in the achievements of psychotherapy, narcology, and social psychiatry, with their more varied forms and methods of work, that fall outside the repertoire of traditional classic psychiatry. Mental medicine, whose polymodal structure is aimed at the *wholesome* holistic approach to mental illnesses, that considers not only nosological categories, but also *potential risks* of their formation can be the new base for implementation of the new synergetic philosophy in the mental health field.

Table 3. System synthesis of mental medicine

№	Criteria	Clinical psychiatry (thesis)	Anti-psychiatry (antithesis)	Mental medicine (synthesis)
	<i>Philosophy</i>	Positivism, neopositivism, scientism	Existentialism	Synergetics
	<i>Concept</i>	Nosocentricity	Existential freedom of personality	Health-centricity
	<i>Priorities</i>	Clinical	Social	Holistic
	<i>Trend</i>	Biological	Socio-psychological	Bio-psycho-socio-moral- spiritual
	<i>Strategy</i>	Treatment of mental illnesses	Individual mentality	Preventive correction and treatment rehabilitation
	<i>Aims</i>	Return of mental health	Implementing individual rights and freedoms	Improving quality of life and mental health levels
	<i>Tasks</i>	Removing the symptoms	Maintaining the subject's right to his or her uniqueness	Preserving functions and mental potential
	<i>Objects</i>	Sick person	Psychiatry as the ψ -functional institution of authority	Healthy person – client- patient
	<i>Focus</i>	Mental disorder	Peculiarities of interpersonal interaction	Normal – changed – unbalanced mentality
	<i>Technologies</i>	Treatment, rehabilitation	Communication	Preservation – optimisation - recovery
	<i>Process</i>	Hospitalisation	Liberalisation	Adaptation – socialisation- humanisation – re- adaptation
	<i>Dynamics</i>	Linear	Counter-linear	Multidimensional
	<i>Relationship</i>	Paternalism	Protectionism	Partnership
	<i>Ethics</i>	Stigmatisation	Presumption of mental uniqueness	De-stigmatisation
	<i>Forms of implementation</i>	Hospital, clinic, care home	Therapeutic communities	Systematic monitoring of mental health

Considering that mental illnesses consume up to 50% of the budget in developed countries' healthcare systems, the central task is the answer to the sacramental question – what is more effective socially and economically, more clinically viable and humane: to preserve the subpopulations with mentality disorders in their changed reality or to bring them to a legitimate reality which they do not accept? Mental medicine provides the answer; it allows the strengthening of mental health in multiple scenarios and the treatment of mental illness. Mental medicine allows us to justify and implement a worthy care path and fate for any patient or client with specific resources of the polymodal mentality in an adequate for him or her multicultural or virtual hospital reality.

The dialectics of history in general and scientific research in particular are made up of the stages of “throwing away the stones” and their “gathering,” meaning, respectively, processes of analysis and synthesis. However, in essence, they are just procedural thesis and antithesis, and this dyad demands its own logical conclusion, which must be the third stage – construction of the new Cathedral of Science from the gathered stones. This stage can be called the system synthesis of mental medicine.

2. TERRORISM AS AN OUTCOME OF THE DEMORALIZATION SYNDROME

The terrorist attack in Volgograd (December 2013) and its following media coverage “exploded” Russian public conscience and revealed the existing exhaustiveness of traditional obstructive strategies used to counteract suicidal terrorism.

The experience of other countries demonstrates that one must not respond to terror with terror as it only spurs violence and the spiral of terror unwinds even further. That is why the announced formation of a new antiterrorist unit in the city of Volgograd (07.01.2014) was perceived by terrorists as an official recognition of defeat from Russian authorities and a call for expanding the geography of violence. The serial murders in Stavropol (January 2014) became a continuation of this antiterrorist scenario. Psychologists have spent many years discussing the phenomenon of terrorism and compared it to a flood when antiterrorist measures are an attempt to scoop out water with a teaspoon: “Personally addressed counterterrorism only procreates terrorists” [23].

The escalation of terror and state counterterrorism represents the best way to eliminate countries and peoples. Every day we can find the confirmation of this fact in our “mental TV sewerage”, it is present even on family and history channels. Thus, hundreds of millions of TV viewers all over the world enjoy a wonderful TV serial “The Magnificent Century”. It draws a bright and convincing picture that shows how the awe of unmotivated death, terrorism and state counterterrorism created the great Ottoman Empire. The same terror, having reached its apogee and worldwide protest reaction (that was caused by the barbarian genocide of Armenians) destroyed the Empire and made it possible for Atatürk to create a secular republic. This republic has recently undergone the difficult times of “Islamic reformation”.

Since ancient times terror has been the most archaic way of governing people and societies. In the contemporary technological-virtual world it is acquiring new epidemic features that symbolize the completion of another global civilizational cycle. The point here is that *terror itself has become the universal form of war prosecution*, it has radically changed the concept

of warfare and armed forces. There is no front line and there can be no battle line in the contemporary world, that functional and organizational army infrastructure is a thing of the past, it has lost its efficiency with the parity of space military forces.

Ten years ago it was possible to try and compare terrorism and guerrilla warfare, terrorism and revolutionary violence, terrorism and struggle for national liberation. In the past this comparison could be based on the subject's position and on differential diagnostic evaluations. Today there are practically no alternatives – it is more and more obvious that terrorism is becoming a new universal form of war prosecution. In this new quality terrorism demonstrates independent epidemic mechanisms of self-development and has nothing to do with the traditional reasons and factors that used to provoke it in the past. Terrorism is becoming an independent tool for solving political problems: “The future picture of the world is no longer possible without terror and violence” [6].

The notion of civil population is disappearing from our lexicon, and what we have left is *already dead and still alive, everyone is contused by the informational explosion waves brought by the pandemic of terrorism*.

The special feature of the Volgograd tragedy is the fact that, for the first time, Russian mass media stopped spreading explosive informational waves of this attack and damage the public conscience of the country. To intimidate and demoralize a society – is the objective of terrorists, it is not the objective of mass media. Russian leading psychologists have been discussing the necessity of censoring reports on terrorist attacks for 10 years.

It is possible to try and link the tragedies in Volgograd and Stavropol with the preventive intimidation of Russia before the Olympic Games in Sochi. But it is much more important to see and hear another communicative message from terrorists – “Russia is destroying itself”, and it happens because more and more frequently (according to Russian mass media) terrorists are of Slavic origin.

Sorrowful information about civilian casualties and the *consequences of yesterday's failed “Volgograd battle”* are known, with the active phase of the antiterrorist war only beginning. It is important to learn the lesson in a timely manner and make adequate conclusions by building a system of effective defense.

Long before becoming suicide bombers terrorists themselves became victims of *mental terrorism* – destructive manipulation with their conscience in extremist camps, gangs, and armies [31]. As a result of this “brain wash” they developed a fanatic belief in their messianic and self-sacrificing role of fighters against the “infidels”. The outcome of *terrorist demoralization syndrome* manifests itself in the deranged formation and deranged development of moral feelings, cast of mind, social position, and behavior, which are responsible for personal moral socialization.

The ontogenetic approach forms the foundation of this definition. Derangements in the formation of *primary moral feelings* (conscience, duty, faith and responsibility) are most often predetermined by spiritual and moral deficit as well as by family ambivalence. Such derangements develop even above orthodox and pious backgrounds as well as above patriarchal characters.

During adolescence derangements in moral socialization cause a delay and disharmony in the development of *moral make-up fundamentals* – such as patience, tolerance, mercy, humanism, honor, and dignity. At the same time manipulative characteristics of conscience and susceptibility to nationalistic provocations with xenophobia begin their formations.

Derangements in the formation and development of the *spiritual and moral position*, accumulated in the personality's motivational and mindset complex, manifest themselves by the decreased ability to differentiate between good and evil, friendship and love, amorphous personal position and low level of self-criticism in everything that does not include the categories of "infidels" and "strangers", inability to see life perspectives, pessimistic and catastrophic perceptions of the world, capitulation before encountering difficulties sublimated in sacrificial struggle, inability to realize the value of human life.

As a result of the *terrorist (fanatic, extremist) demoralization syndrome* there appear: a complete loss of the socially accepted moral norms of behavior, demonstrative neglect of traditional concepts concerning what is due and what is unallowable, rejection of any moral duties and moral self-control, inability to act independently and irresponsibility for one's actions, increased suggestibility and dependence, complete devaluation of legal awareness and law-abidance, loss of social and personal identity. All this allows a militant-manipulator to easily "create" new generations of suicidal terrorists. The recruitment of suicide terrorists looks even more tragic and dramatic when it comes to women, aged people, mentally ill and disabled individuals, teenagers and children. On January 08, 2014 the 1st Russian channel reported a story of a 10 year old Afghan girl whose farther and elder brother were forcing the child to become a suicide attacker. It was a miracle that she managed to escape and reach the police station that she was supposed to explode by the order of her relatives. This story reflects the monstrous *family variant of the terrorist demoralization syndrome*, when parents are ready to send children to their death. In this case it is not so important whether they do it for money or fighting for an "idea". Any form of terrorism inevitably destroys and eliminates individual human lives of terrorists as well as the lives of family members who support it. That is why from the psychiatric point of view terrorism represents the most destructive form of the *epidemic suicidal behavior*. To launch and support such destructive social epidemics of suicidal terrorism three conditions are sufficient and must be met [41]: religious culture of martyrdom, decision of a terrorist organization, possibility of compulsory but made to appear as voluntary recruitment of future suicide attackers.

The development of demoralization syndrome has multiple variants in the ethno-cultural environment. It has minimum dependence on the intellectual potential and quality of education. Terrorism, like alcoholism and drug addiction can derive from rich and poor backgrounds. There is no coincidence that the number one and most mythologized terrorist of the world Ben Laden came from a well-educated and wealthy family.

3. TERRORISM AS DESTRUCTIVE SOCIAL EPIDEMICS

Demoralization syndrome – is a moral and psychological foundation of any social epidemic regardless of its form: drug addiction, fanaticism, extremism, terrorism and many others.

Social epidemics– is the appearance (outbreak) of a social decease in a community (or on a given territory) when the rate of this decease exceeds regular expectations. Social epidemics become *destructive*, when they begin to threaten the national security of a country as a whole. This is when the mechanisms of social ailment generation and their extensive and uncontrolled reproduction become active and transform an epidemic into a *pandemic* that can overtake not only countries but also continents [6].

Generalization shows itself in the form of new infringements when more serious and punishable social norms are more and more often violated. Thus hard drinking primarily represents a phenomenon of immoral behavior that breaks ethics rules. It is followed by alcoholism that represents a medical/psychiatric condition which is likely to result in administrative infringements of the law after which some of the patient's rights will be restricted. Sever forms of alcohol abuse or alcohol psychosis are bound to unlawful behavior and criminal responsibility.

Extended reproduction shows itself in a highly latent form of social ailments. At best, every out-patient department for drug addicts has an official record of only 1 alcoholic out of 10. Furthermore, it has an official record of only 1 drug addict out of 30 habitual abusers. The remaining addicts successfully continue their personal destruction together with the destruction of their families. They get new generations involved into the consumption of drugs. The first vacant place is always reserved for youth. We have the same situation with grave crimes and AIDS because only 1 case out of 5 is detected. There exists no accurate statistics or estimation that could reflect the actual spread of tuberculosis, STDs, corruption and prostitution, gambling addiction, extremism and fanaticism as well as many other problems.

The uncontrollability of social epidemics is predetermined by the absence of a mental health monitoring system and the presence of immediate interdepartmental barriers that exist in organizations with preventive and correctional missions as well as in treatment and rehabilitation clinics.

Epidemiological recognition of the threats and challenges posed by terrorism and extremism is not another myth or banal abuse of psychiatric terminology. It is not what happened in the case of trappidomania diagnosis or so the called pathological craving for freedom among American slaves, delirium of reformation, and criminal prosecution of homosexuality in the USSR. Today clinical psychiatry makes diagnoses, which yesterday were viewed as a purely social phenomenon. For example, the Mobbing syndrome evolved from banal "office wars". Today it is a form on non-lethal mental terrorism that destroys the mental health of its "Mobbing targets" and corporate society.

It is of fundamental importance to note the unity and universality of the social epidemic base. Drug and alcohol addictions, crime and violence, extremism and terrorism unite the subpopulations of people "exiled" from the normative social systems [1].

The following [6] groups of conditions initiate the epidemiological spread of terrorism:

1. *formation of the information society*, that indefinitely spreads the potential effect of terrorisms;
2. *vulnerability of the technological environment* that is responsible for human existence, it makes the pinpoint destruction of the technological environment's social, natural, and technological foundations possible;
3. *smearing of the traditional society* with modernization and liberal values: concept of the social contract, ideas that proclaim state authorities responsible before their society, ideas promoting the value of law and human life;
4. *crisis stages of social development* accompanied by the ideas of separatism, religious, ethnic, and ideological conflicts.

Terrorism represents one of the most polymodal types of *destructive social epidemics*, its working classification includes:

1. *Social epidemics of dependent disorders:*

- a) chemical: alcoholism, drug addiction (drug dealing is the financial foundation of terrorism) and others;
- b) non-chemical: gambling and others;
- c) vicarious, those that fill moral and psychological emptiness: workaholism, sectarianism, radicalism, fanaticism, extremism, mental terrorism and others;
- d) electronic: internet and computer (cyber terrorism) and others;
- e) changing people's dietary habits: dietmania, manipulative nutraceutics (nutritional supplements) and others;
- f) expansive forms of sexual self-assertion: public group exhibitionism, hypercompensatory sex parades and others.

2. *Social epidemics of induced disorders:*

- a) early hysteria-demonic: manarik and emiryachenie (Yakut hysteria), lishinka and kila, ikota and sheva (that require to "draw blood" of the chaki - a sorceress who put an evil curse, in order to regain health) and others;
- b) hysteria-demonic renaissance: shamanism, magic, sorcery, pseudo-religious extremism and terrorism and others;
- c) induced nervous-psycho disorders: somatoform, social - stress and others;

3. *Epidemics of social ailments:*

- a) infectious diseases: especially dangerous infections (bio-terrorism), tuberculosis, AIDS and others;
- b) psychic disorders: mobbing-terrorism, social phobias, panic reactions to terrorist attacks and others;

4. *Epidemics of sociopathy:*

- a) suicidal behavior: suicides, suicidal terrorism and others;
- b) organized serial crime: terrorism, corruption and others.

Terrorism is an exceptionally polymorph phenomenon with different types and classes of usable aggressive agents. That is why it is present in all four groups of the suggested classification. Thus, the arsenal of bio-terrorism includes 13 types of viruses, 7 – bacteria, 3 – rickettsiae that cause dangerous infectious diseases, 12 microbial toxins. Long ago special methods of diagnostics and therapy have been developed to counter these threats.

The situation with *mental terrorism* appears to be much more dramatic. This form of terrorism affects mental health together with ideological, spiritual, and moral bases of culture, society, and statehood. Furthermore, it is followed by the stirring of national hatred, depreciation of spiritual and moral values with their ideals, marginalization and criminalization of social consciousness. This is an everyday reality for Russia while it keeps on sinking in the "waterfalls of mental TV sewage". As a result of this phenomenon there developed increased uncertainty about tomorrow and hesitancy about the state, profound sense of anxiety, aggression and emotional instability, suggestibility and trustfulness, distrust to official information with preference given to rumors, decreased criticality [31, 43].

Such peculiarities of the public consciousness are characteristic of emergencies. It turns out that in Russia the state of emergency, caused by mental terrorism, exists de-facto, but de jure the society is already unable to perceive it adequately. Furthermore, public consciousness and the Russian state itself are undergoing painless destruction under the anesthetization of the mental TV-sewage. This image has a serious associative and medical interpretation. Psychiatric

practice has encountered and described cases of cloacae gas poisoning that lead to the instant death of the cerebral cortex and visualize in the form of profound encephalopathy (hydrogen sulfide intoxication can be in-plant or take place in natural environments: areas of natural gas release, around sulfurous mineral waters, in deep wells and pits, with rotting organic substances that contain sulphur). During my 40 year clinical practice there have been only several cases of such intoxication. For example, when construction workers opened airtight pits half of them died and the remaining half acquired dementia. With this decease they produced the impression of preteens. All this really reminds me of the situation on the Russian television where infantile intonation is being used in order to facilitate the manipulation of human consciousness.

It is the decrease of the stress-resistance threshold by means of the infantile *reverberatory* tuning of public consciousness through electronic mass media that allows exploding the public consciousness with the informational shock waves of any terrorist attack or any kind of emergency. The chain reactions of anxiety and fear are multiplied and doubled. Their cumulative effects are amplified as they provoke different kinds of induced socially stressful and somatoform neuropsychic disorders. Today's mass media policy significantly favors this harmful influence. It relies on the "sinister charm of violence and fear" [7, p. 432] and is guided by the principles like "corpses make our picture more alive" [7, p. 428]. This is how mass media imprints the image of our contemporary society on the public consciousness. It is the society of utter and unpredictable violence. Due to perverted professional ethics and esthetics the media coverage of any terrorist attack or tragedy literally turns into a "satanic necrophilic feast" that creates epidemic waves of induced disorders.

The following classification of social epidemics can be based on their epidemiological scale:

1. social epidemics (all forms);
2. destructive social epidemics (all forms);
3. generalized destructive social epidemics: nationalistic bashing and massacre, "color" revolutions, genocide, civil wars and others;
4. pandemics of destructive social epidemics: drug addiction, terrorism, corruption and others.

The world epidemics of drug addiction and terrorism are closely interconnected. According to the American Drug Enforcement Administration, 39 % of terrorist organizations are associated with drug dealing. The global volume of drug traffic, according to different estimations, makes up from 400 to 1 000 billion dollars every year. There is no coincidence that the former president of Columbia M. Pastrana called drug dealing "the main financier of terrorism and death in the world" [27]. One can easily add here the total corruption that systematically embraces the entire civilized infrastructure and creates premises for *planetary suicide*.

Social epidemics become *generalized* as a significant percentage of the dependent subpopulation (population suffering from dependent personality disorders) gets involved. According to our data, it makes up 30 % of the whole population.

The first generalized social epidemics in Russian history was "Smutnoe vremya" (the Time of Troubles), that ended about 400 years ago. It was accompanied by large scale hysteria-demonic and infectious epidemics, plunder, robberies and demolitions, burning of witches and

magicians, appearance of various impostors, summoned and recognized by the corrupt elite. The whole country and its population have remembered this lesson for 300 years and it was only in 1917 when the October revolution demonstrated its blood red results and dramatic scenarios.

The student disturbances in Paris (1968) are an example of a *bloodless color revolution* in the contemporary European history. The organizers of this coup d'etat who overthrew president Charles de Gaulle gave young people a possibility to “let off some fume” on barricades. That protesting youth was sincerely engrossed with the ideas of Sartre and was held captive by the romantic illusions of Anarchism and Trotskyism.

Today the mental design of the technological-virtual world (which is composed of numerous ideas and illusions) quickly changes its arrangement of the public consciousness and it happens as if somebody unnoticed swings his mighty wand to conduct the show. One way or another, the newest generations of “color” revolutions industrialized the strategies, tactics, forms and techniques of destroying traditional, natural, cultural and socioeconomic structures of countries and people for the benefit of the financing party. That is why it is extremely difficult to develop a spiritual immunity to all kinds of social epidemics; the development of such immunity has become one of the major priorities of the state. Spiritual immunity is composed of moral and value-based potential of a personality realizing its unity with countrymen and motherland. Here is no coincidence it is the spiritual culture that happens to be the first target of the contemporary aggressor.

Anomia forms the foundation of any destructive social epidemics, it becomes apparent when fundamental moral values of a system get corrupted. Contradictions typically develop between the announced objectives and the impossibility for the majority of citizens to accomplish them using traditional methods. It results in the personality's isolation from society and depressive disillusionment in life. Anomia favors the spread of permissivity – destabilization and the abolishment of socially accepted prohibitions that are structural and ethical elements of society. In such conditions any person can lose his supporting point and be left without his system of moral values as well as support of traditional public morals. All this creates basic conditions for the recruitment of individuals among the dependant subpopulation and their further participation in different forms of destructive social epidemics. The most tragic form of these epidemics is terrorism.

4. FORMS OF TERRORISM AND MECHANISMS OF PERSONALITY DEFORMATION

Terrorism (from Latin *terror*) – is a weapon of mass destruction, that combines direct physical damage of the victims with the significant damage done to the bio-psycho-socio-spiritual resources of a society. The meaningful content of terror is restricted to three characteristics: act of intimidation, request of submission, meaningful content [6, 23, 31].

Generalized psychological portrait of a terrorist [45, 30, 31, 41, 43] most often includes the following characteristics:

- young people around 20 (+/- 5);
- patriarchal or highly religious family culture;

- dominant view about some historic injury of his nation;
- deep emotional connections with his ethnos;
- anxiety about pinched national pride;
- distorted and mythologized views about some historical insulters and need for revenge;
- topical psychological injury, often this injury is caused by the death of relatives in front of the future terrorist;
- early deprivation of parental care and attention;
- deficit of emotional connections during childhood;
- high level of pretensions that showed up since childhood, overrated self-esteem, tendency to fantasize and demand of increased attention;
- as a rule “black sheep”, outsider among his peers;
- disposition towards aggression and vandalism;
- often has obvious or hidden physical defects;
- traumatogenic youth with privations, humiliations, bereavement;
- disturbance of moral socialization;
- settlement of conflicts only through violence;
- difficulties with adaptation to social principles and regulations;
- seeking recognition and self-assured;
- prevalence of hysteric explosive traits of personality;
- high level of neurosis and frustration;
- personality disorders with high level of aggression and self-actualization;
- submission of one’s individuality to group identity;
- high impulsivity, inclination to immediate actions.

Among the most characteristic *mental peculiarities of terrorists* [45, 15, 30, 31, 41, 43] it is possible to single out the following features:

- displacement of time perception (present includes past);
- archaic and binary picture of the world;
- disappearance of borders between reality and fantasy;
- infantilism and naivety, high suggestibility;
- primitiveness of cognitive styles;
- presence of apocalyptic feelings and fantasies;
- ideas of messianism, unique purport of life and sacrificial service;
- ambivalent sadomasochist position;
- identification with aggressor;
- no receptiveness to counterarguments and dissuasion;
- loss of pragmatism and rationality;
- religious arrangement of ideas promoting struggle and revenge;
- cultivation of conceptions about death and life after death;
- glorification of sacrificial death and the heroic deeds of martyrs;
- absence of fear and repentance;
- derangements in the formation and development of moral feelings (conscience and duty, faith and responsibility), character (patience and tolerance, mercy and humanism, honor and dignity), position (ability to differentiate between good and evil, expression of friendship and love), behavioral ethics and communication;

- predilection for illusory-compensatory way of satisfying one's needs instead of active and creative;
- tendency to quick, final and easy solutions;
- primitive mythologizing and sign-symbolic mediation of one's primary activity with compulsory emphasis made on the list of enemies;
- utmost, terminal and artificial dramatization of the situation;
- loss of tactical prognostication resources and vision of strategic perspectives in life.

Contemporary terrorism is characterized by the galloping tempos of its cruelty growth, usage of newest lethal and non-lethal weapons, cyber and nanotechnologies, expanded reproduction of terrorist movements' quantity, generalization and globalization of their activity scale, high level of organization and professionalism, sacrificial fanaticism and shocking corruption. It is not without reason that long time ago Israeli psychologists came to the conclusion that it is impossible to reconstruct or reform the personality of convicted terrorists. This conclusion might be connected with the fact that quite recently special antiterrorist units all over the world began to liquidate terrorists rather than detain them. However attempts to find corrective methods have not been stopped. Thus, neurobiologists from the Oxford University made an announcement about the development of a pilot technology for treating Islamic fundamentalists. This announcement was made two weeks after a shocking public murder in London when two Nigerians cruelly killed a soldier of the British army (Lee Rigby) [8]. The technology includes both biological methods and psychotherapeutic sanitization of extremist beliefs. Moreover, the scientists have suggested that "radical attitudes" should be classified as psychic disorders! It was revealed that the British security service MI5 had attempted to hire one of those Nigerians six month before the terrifying murder took place. This episode really reminds of the contacts that the Russian special service had established (as reported by the Russian mass media) with one the Volgograd suicide bombers prior to the terrorist action in the city. It means that in the struggle against terrorism one cannot rely solely on special services. They simply cannot have all necessary information to prevent such acts of terrorism. These tragedies have demonstrated that the approach towards terrorism requires a systematic synergetic review. It goes without saying that special operations and systematic monitoring of the information field are absolutely necessary antiterrorist activities, however, fighting against destructive social epidemics of terrorism requires, figuratively speaking, *adyke of spiritual immunity that is structured by the moral and value-based potential of the population and cemented with the energy of creative and rallied nation.*

It is deeply symbolic that last year the world mass media proclaimed the president of the Russian Federation V.V. Putin a *spiritual leader of humanitarian anti-terror* after the threat of Syria's terrorist annihilation was overturned with the help of Russia. Of course opponents have not forgiven Russia and Putin for that and the tragedies in Volgograd and Stavropol serve as evidence of this fact.

The classification of terrorism forms includes: ideological and religious, political and ecological, chemical and physical, nuclear and biological, psychological and suicidal, spiritual and mental forms. According to its territorial scale terrorism can be classified as corporative (including the syndrome of mobbing-terrorism in "office wars"), municipal (for example in Volgograd), provincial, regional (republics of the Northern Caucasus), federal, international.

We have singled out [31] the following mechanisms of exposing influence on personality in extremist and terrorist organizations. These mechanisms lead to the practically irreversible deformation of one's personality.

1. *Monologue* – unidirectional impact that excludes alternative sources of information.
2. *Mythological* – use of tested mythological schemes that inspire to die for some idea.
3. *Emotional* – compensation of emotional feelings and care that were not received in society.
4. *Collectivism* – use of group forms self- and mutual induction: training “referent group” prepares a suicide terrorist and leads him till the very end.
5. *Counter argumentation* – suggestion of counter arguments to anticipated doubts and contradictions that is done in advance.
6. *Intolerance* – stimulation of suggestibility in the background of psychophysical exhaustion, especially in field conditions and underground.
7. *Selectivity*– recruitment of suicidal terrorist among the most non-adapted and deficient people.
8. *Manipulative* – use of an extensive psycho-technological arsenal of suggestion.
9. *Paranormal* – use of fictional achievements based on supersensory experience.
11. *Controllability* –ensuring total control of personality and his behavior.
10. *Ritualistic*– creation and nailing down of behavioral habits and models of killing and committing a suicide.

Teaching hatred and brainwashing have three objectives:

1. to deny a positive emotional evaluation of the enemy;
2. to cultivate malice and fear (a classical example of it can be found in the novel of D.Orwell “1984” «five-minute periods of hatred»);
3. generation of decisions based on mistaken cognitive conclusions and faulty critical thinking [42].

The model of psychology of hatred developed by Robert Sternberg [42] has three components and the following blocks:

1. Disgust or rejection of closeness with the enemy. Its source can be found in the peculiarities of the subject's personality, his own actions or propaganda.
2. Passion as a measure of emotional energy, connected with the dynamics of hatred, described in the terms of fear emotions, malice and rage.
3. Obligation that consists of two components: cognitive aberration to decrease the value and significance of the hated group of people: individuals who compose it are viewed as not quite human and very often as “subhuman”. Its second component is behavioral; it is a decision to struggle, use violence an even die.

Interaction between these three elements allowed the author [42] to single out six types of hatred:

1. Hatred expressed in the form of *disgust* towards a hated group (for example a nation).The subject does not want to have anything in common with them because they, from his point of view, have very little in common with people.
2. «*Furious*»hate is expressed in extreme emotional manifestations of malice and fear and it can lead to violence or attempt to avoid the threat that is (in the view of the hatred subjects) posed by the hostile group.
3. «*Cold*»hate that is characterized by the perception of a hostile group as low and mean.
4. «*Boiling*»hate that combines disgust towards a hated group with the need to illuminate the threat that this group poses.
5. *Hardly restrained* hate is characterized by the feeling of constant disgust and fear; at the same time the hostile group is perceived as a gathering of “supermen”.
6. «*Burning hate*»this type of hate is associated with feeling of necessity to physically exterminate the hated enemy. In this case all three elements of hate are present and this type of hate most often becomes the subject of study in frames of terrorism research and studies.

This is how –*through brainwashing and teaching hatred*– the personality of a future suicidal terrorist gets destroyed in order to turn him into a simple “means of transportation”. Only the organizers get the greater part of the client’s reward. There is nothing personal here. Some action appears on TV screens and a sum of money is transferred to someone’s bank account. *A terrorist war* is a business for its organizers and bloody politics for the ordering party.

5. MENTAL SYNERGY OF TERRORISM

The conventional and generalized synergetic concept that demonstrates the development of social epidemics of terrorism is presented in table 1. The illustration to this table shows only the basic markers of this dynamic disorder which has a great polyvalence and multivariance; those markers are connected with the clinical psychopathological and somato-neurologic, socio-psychological, spiritual and moral personal topologies as well as the forms and trajectories of epidemic development.

To make it more convenient for perception, the model of synergetic epidemic is presented in the flat-bed projection even though it is multidimensional, non-linear and unlocked. Its trajectories of development are set and corrected in the points of bifurcation demonstrating multivariance and strombuliform. Non-linear discreteness and fractality have come to replace the nosocentric dynamics with its traditional its stages. Fractal — is a projection onto the wide natural-science field of quantum views. Fractal — is an integral of the dissipative system development that has its inner mechanisms of self-organization, self-development, multivariate trajectories of motion in the multidimensional space. Table 1 demonstrates only the progredient variant of the terrorism epidemic development, it shows four interdependent planes of sociogenesis, psychogenesis, somatogenesis, and animogenesis. The epidemic nature of this disorder and its individual trajectories of development are defined by the unique combination of different bio-psycho-socio-spiritual factors, effectiveness of defense, compensatory and adaptation mechanisms, methods of mental preventology and mental medicine.

Animogenesis (ontogenetic spiritual and moral development of a personality) begins in the fractal of *predisposition* — *mobbing family* (and/or environment), it is distinguished by *spiritual and moral deficiency* and ambivalence, high frequency of asocial and dependant disorders of parents and close relatives, various forms of violence, harassments, cavils, intimidations, insults, mockery, rudeness, deception, moral pressing and isolation.

Early imposition of the “mobbing target” image on children and adolescents leads to “mobbing sensibilization” of the inner world, formation of perverted and simplified mental models of interpersonal interaction and behavior. This family and millisocial environment have anomic and permissive nature, they are very likely to marginalize and dehumanize the moral values of a personality.

During the *latent fractal of bullying diathesis* defensive and compensatory, spiteful and aggressive protest reactions of behavioral nature develop for self-assertion; they increase the polarization of relationship and isolation.

The formation of primary moral feelings is disturbed: conscience, duty, faith and responsibility.

The deformation of spiritual development shows itself in the form of distorted self-esteem and failure to understand the purport of life, unreadiness to act independently as a full-grown individual, undeveloped moral self-consciousness and moral responsibility.

In the initial fractal of crowding mass outbreaks (mass forms of sadistic aggression and vandalism) a *deformed moral image* becomes fixated through training and behavioral practice in street teenage gangs and groups, various legal and illegal fan movements, radical and extremist movements; it lays the corner stone to the development of the demoralization syndrome. Delay and disharmony of the development of the moral image foundations show themselves as the absence of tolerance, patience, mercy, humanism, honor, dignity, deficiency and disharmony of creative potential in spiritual, figural and productive activities; unreadiness and inability to be professionally and socially labile, inability to maintain continuous development and education; manipulative capability of consciousness, susceptibility to nationalistic provocations; painful emotional stress caused by strangulated national pride and xenophobia; exceptional stereotypical reactions to challenges and difficulties – aggression and vandalism.

In the debut fractal of the social epidemic of terrorism the pro-social spiritual and moral position of personality is lost and the syndrome of terrorist demoralization is formed; at the same time the abilities to differentiate good and evil, friendship and love decrease. An affected personality becomes amorphous and deficient, low self-criticism develops together with the personality’s impairment. The vision of life becomes stereotyped with the only purport of life being the struggle for the right and the inability to realize the value of human life. Crowding terrorists are distinguished by the archaic and binary ethical picture of the world that has blurred borders between reality and fantasy. They are fixated on dominant ideas of the nation’s historical trauma and perverted mythologized image of the enemy. Crowding terrorists remain prisoners of their obsessions with messianic ideas and believe in a special meaning of life that infers selfless service in the name of justice and historical revenge. They distinguish themselves with easy perception and neglect of multiple adaptation difficulties to social conventions and moral rules, inclination to “solve problems” only with the help of quick and easy solutions based on violence, preference to primitive styles of mental representation, and armed aggression, religious ritual coverage of their struggle for the right, cultivation of heroized ideas about martyr death and redemptive life after death.

The fractal of chronization of the destructive social epidemic of terrorism is characterized by different forms and types of immoral and illegal behavior development; this behavior threatens the national security of a country. The syndrome of terrorist demoralization shows itself as a complete loss of the socially accepted mediated moral behavior that is based on the concepts of good and evil, indebted and unacceptable, demonstrative disregard of any moral duties and rejection of moral self-control, dependence and irresponsibility of personal actions, inability to carry out moral self-evaluation of one's behavior and inability to respect the ethical norms of business communication, loss of personal and social identity, devaluation of legal awareness and law-obedience, avoidance of personal moral choice making as well as any kind of responsibility. The anonymity of cyber-terrorists and facemasks on participants of terroristic civil wars demonstrate it.

The fractal of outcome is characterized by the maximum epidemic level of pandemic, terminal complications and consequences for the society and terrorists. The ethical component of personality's difficult asocial development makes terrorists absolutely insensitive to counterarguments and dissuasion. Together with comorbid and associated disorders it leads to mental defects, results in the loss of pragmatism and rationality, absence of fear and repentance, super- glorification of sacrificial death and heroic martyrdom in the terrorist civil war.

All this allows militant manipulators to "create" new generations of suicidal terrorists easily. *In fact, they are engaged in mental terrorism – individual, distractive and mercenary creation of adherents.* The only difference of mental terrorism from traditional forms of propaganda and agitation is in the population format of the public consciousness, that is "being attacked" by mass media. The growing network interactivity of the global world is making the information front line the primary battlefield in the war against terrorism.

Serial and deadly equifinal terroristic wars develop according to the mechanism of a dependant disorder when only an injurious act of terrorism can provide a psycho-emotional relief and fill a desperate and inescapable existential situation with illusionary meanings. These illusionary meanings are literally covered with the masks of "unknown soldiers".

The development of the terrorist demoralization syndrome is exceptionally multivariate, it is predetermined by the initial ethical topology of personality, ethno-cultural and socio-economic, religious and political factors of the environment. The latter factors are turning into a dehumanized and demoralized "*terroristic world*" that is *undermining the civilizational foundations of humanity.*

Sociogenesis (ontogenic development of social roles and relations) in the fractal of predisposition is characterized by the high frequency of various disorders in the structure and functions of the mobbing family. They substantially predetermine the mental representation of destructive cognitive models of disharmonious interpersonal relations: the cult of strength and aggression, humiliations and insults, social deprivations and isolations, negativism and protest.

In the latent fractal of bullying diathesis the dispersion and inversion of the "mobbing target" and "mobbing terrorist" take place as a result of the personality's maturation and socialization disorders. These disorders develop in a disharmonious millisocial environment and are later followed by the "bullying terrorist" whose distinctive features are hyper-compensatory cruelty and aggression. Such personalities do not have psychosocial resources for productive self-realization through their professional and educational activities, inside their families and social networks. To a significant extent that is the exact reason why non-pathological dependant behavior develops through compensatory mechanisms.

Table 3. Fractal dynamics of epidemic development of terrorism

	Prenosological fractals			Nosological fractals		
Vectors of ontogenesis	Predispositions: mobbingogenic family and/ or environment	Latent: bullyingogenic diathesis	Initial: mass crowding	Debut: Social epidemic	Chronizations: Destructive social epidemic	Outcome: Pandemic and terminal complications
Somatogenesis	Hereditary somatic burden	Derangements of neuroprocesses	Somatoform dysfunctions	Somatized disorder	Comorbid psychosomatic illness	Somato-neurological complications and degradation of public health
Psychogenesis	Psychopathological burden	Polymodal psychopatization of personality	Asocial and/or dependent personality outside personal space	Asocial and /or dependent personality disorder	Asocial and/ or dependent personality development	Psychic defect and destruction of public consciousness
Sociogenesis	Derangements of structure and family function	Derangements of personality socialization	Non-pathological dependent and /or asocial behavior	Pathologic dependent and / or asocial behavior	Social decompensation	Social disadaptation and dehumanization of society
Animogenesis	Moral and spiritual family deficiency	Derangements in moral feelings formation	Deformation of moral image	Loss of moral position	Amoral and unlawful behavior	Serial criminality and suicidal terrorism, demoralization of public consciousness

It is characterized by perverted obsessive fantasies that are realized through sadistic and cruel compulsive group tortures of defenseless animals and vulnerable peers, subordination of personal interests to some kind of paraphilia, long fixation of attention and, decreased ability to control, immersion into asocial dependence, dependency and passivity when choosing behavioral strategies and verbal response strategies, self — and mutual induction during *mass outbreaks of crowding terrorism in the initial fractal*.

In the fractal of the social terrorism epidemic debut the reference nucleus of the epidemic hotbed and its leaders display *pathologic dependent and asocial behavior*; it is notable for the episodes when changed conditions of consciousness are present at the moment of psychological and physical dependence realization, irresistibility and compulsivity of the asocial activity, stereotypization of the terroristic lifestyle, cancelation syndrome between delicts and acts of terrorism.

In the chronization fractal a destructive social epidemic of terrorism unfolds, it has different instruments and mechanisms depending on the type and form of terrorism, however, it inevitably leads the participants of an epidemic process to social decompensation and threatens the national security of a country as a whole.

In the outcome fractal a total social disadaptation is formed at liberty; in the case of lifetime imprisonment a forced adaptation to the prison conditions develops. The development of terroristic pandemic is accompanied by and matched with various social markers of the global dehumanization crisis and civilization degradation: famine, unemployment, migration, etc.

Psychogenesis (ontogenic development of mental functions) *in the fractal of predisposition*. To a significant degree psychogenesis is predetermined by the premorbid psychopathological complication of the mobbing family, it is distinguished by non-motivated psycho-emotional instability and communicative deficiency. Children who grow in such families, even those with orthodox and patriarchal backgrounds, experience an acute shortage of emotional connections, and painfully go through the early loss of parental care. Trying to compensate for them they develop an aptitude to fantasize and demand increased attention. Very often an early psychological trauma is related to a glorified martyr death of a relative or another close acquaintance that was witnessed by the future terrorist. This death becomes a matrix of mental representation for tomorrow's terroristic lifestyle and death.

In the latent fractal of bullying diathesis addictive radicals of an early psychopathic disorder and personal deformation are formed and fixated, they show themselves as anticipating malicious and aggressive verbal reactions to all challenges and difficulties; they stereotype aggressive and auto-aggressive styles of behavior, launch the mechanism of hypercompensatory "asocial hysteria" and polymodal asocial dependant disorder. Such a personality can demonstrate various socially stressful disorders even in the situation when it encounters banal life difficulties. All this speeds up the formation of a primary dependant pattern, that will be able to change its modality later as well as the form of dependence. However, the asocial radical of this dependence will be steadily preserved engrossing the personality's nucleus.

In the initial fractal of crowding terrorism mass outbreaks behavioral realization of previously learned mental schemes and scenarios of asocial self-assertion takes place, this is the only outcome based on the cognitive and cultural personal resources. An asocial and dependant personality demonstrates vivid realistic reminiscences and fantasies glorifying terrorism outside his disorder. It happens above the background of infantilism and suggestibility, openheartedness and sensory spontaneity, curiosity and high searching activity,

minimalism and egocentrism, impressionability and impatience, aptitude to taking risks and provoking dangerous situations, generalized aggression and vandalism. This personality gets a chance to overcome the inferiority complex of an individual rejected in his prosocial environment and get rid of the “black sheep” label only in street gangs, extremist and fanatic groups. The extrusion and disactualization of such obsessive reminiscences about one’s traumatic youth, that had multiple humiliations and losses, is accompanied by the hyper-compensatory necessity to revenge not only some particular offenders, but the whole cruel and unjust world, revenge for one’s nation. This is how the psychological mechanisms of epidemic terrorism generalization demonstrate themselves.

All 10 types of personality disorders, described in ICD 10, can take place among terrorists and extremists. However, the most significant role in launching epidemic processes belongs to mutually reinforcing asocial and dependant disorders with their radicals. They easily create a TV image that shows the unity of people and their leaders. An epidemic develops according to self and mutual induction mechanisms as it adds complications to the existing personality disorder.

Borderline personality disorder — is a severe emotional instability and impulsive aggression, disturbance of interpersonal relations and self-destructing behavior. Prevalence among population 1,5-2 %.

Personality disorder - are deep-rooted styles of behavior and thinking with rigid response reactions in excessively expressed forms. Prevalence 6-18 % [2].

At the time of K. Schneider [7] not only the afflicted person suffered from this disorder, the whole society was affected as well. Today the epidemic spread of extremism and terrorism mobilizes the mechanisms of induction and generalization, it turns them into a global populational mutation, and poses the threat of civilization suicide. Moreover, it is necessary to take into account the fact that up to 30% of the population suffer from various forms of dependences [4], the controlled social switching of their modality can quickly lead to the emergence of social epidemics.

The debut fractal of the social epidemic of terrorism is most often represented by asocial and dependant personality disorders of the epidemic hotbed referent nucleus. It induces the fellow-fighters who make part of the polymodal subpopulation.

Dependant personality disorders are characterized by the deficiency of normative sociality and widening of the asocial manifestation’s specter, personality deformation and emotional burnout, inability to make decisions independently outside one’s terroristic lifestyle, frequent combinations of schizoid personality features with bad tolerance of loneliness. It facilitates the development of anxious depression, urging an individual to commit excesses, delicts and acts of terrorism that provide a temporary psycho-emotional relief.

The fractal of chronization of the destructive social epidemic of terrorism is represented by multivariate *asocial and dependant personality developments*, terrorism begins to take the leading position in the their constellation and it turns into a dominant dependence. A changing personal and social identity, new cognitive schemes and mental models of business interaction allow moderators to easily find suitable euphemisms (“red brigades”, “right sector” and etc.), and complimentary-compensatory labels (commandant, centurion, national guardsman, etc), although, all this is unable to change a developed terroristic nucleus of a paraphilic personality.

In April 2014 all Russian TV channels showed the recording of Alexander M. (one of the leaders of Kiev Maidan) when he expressed his sadistic threats to the deputies of the regional council; in this video he appeared dressed in camouflage and was holding an assault rifle as if

it was a phallus like prosthesis. In a different video he experiences a masochistic ecstasy from the strikes of female heels against the head. Undoubtedly, internet screening and TV pictures can let us express only a supposition about sadomasochism or multiple disorders of sexual preferences, that are usually represented by a combination of such paraphilias as fetishism, transvestism and sadomasochism. The producers of tragedy could not allow this militant (who sincerely believed in his messianic role of a fighter) to continue his vivid illustration of this clinical case of paraphilia. This “tele-hero” was doomed to failure from the moment of his TV screen debut. *Terror inside a terroristic community is a law of moral anomia in a legion of assassins.* The classification of paraphilia as a dependant disorder [1], the same refers to mobbing, bullying and crowding [6], makes it possible to view terrorism as an independent type of polymodal dependant disorder.

There is no doubt that the participants of mass murders and sexual violence in Odessa's Hatyn, (those that were registered by audio and video devices) will never be found by any international commission.

The weapons of terrorists, besides their direct purposes, serve as a *hypercompensatory attribute that masks*; the inability to make decisions without advice of their senior leaders and financing mentors; readiness to delegate them rights without demur when it comes to making decisions of critical importance; anticipating preparedness to agree with their masters caused by the fear to be rejected (even when knowing that they are wrong); difficulties when starting something independently; readiness of one's own free will to carry out risky and dangerous orders in order to get a reward or appraisal from the principle; bad tolerance of loneliness and readiness to undertake any efforts in order to avoid it; feeling of being drained or being helpless when falling out of one's “national guard”; easy susceptibility and vulnerability to manipulability, enchainment with anxiety and fear to be rejected that pushes to commit new and new delicts and acts of terrorism.

In the outcome fractal one can expect a psychic defect – it differs considerably depending on various forms of terroristic asocial dependencies that range from the syndrome of emotional burn out and destructive professiongenesis with mobbing-, bullying- and crowding –terrorism to the psychoorganic syndrome with traumatic lesion of the brain or chemical dependences.

The escalation of a terroristic civil war inevitably leads to the augmented *destruction of the public consciousness as an integral quality of the nation's mental health.*

Somatogenesis (ontogenic development of somatic functions) refers to the least studied aspects. It is generally accepted that nonspecific hereditary burden (fractal of predisposition), unfavorable intra- perinatal exposures play an important role in it. Different normative psychosomatic reactions can be response reactions to challenges and difficulties; later they transform into functional psychosomatic disorders — organ neuroses (*latent fractal*) and somatoform disorders, they provide a clinical description of an individual with forming “withdrawal syndrome” (*initial fractal*). The severity of possible somatization disorders (*debut fractal*) and comorbid psychomotor disorders is defined by the duration of the “withdrawal syndrome”, unwillingness and inability of a deformed personality to attain psycho-emotional relief in frames of his adaptive and prosocial behavior (*chronization fractal*).

All forms of social epidemics are characterized by the absence of parallelism in the expression of mental and somato- neurological, moral and spiritual, social and psychological disorders. While chemical dependences during their somatogenesis result in the evolution of the given disorders and are strongly connected to the toxic agent, the non-chemical ones (as a compensatory variant of development) more often lead to comorbid psychosomatic disorders.

The accepted name of this mechanism is somatization of dependence. *In the outcome fractal* one can expect different somato-neurological complications; as for the level of social health – regress and degradation can be expected. The notion of comorbidity is not so much based on traditional views about compatibility of pathologies but on etiopathogenic unity of all dependent behavior forms [3].

Dependency signs may stipulate dangerous aggressive actions in frames of self- and mutual induction of social terrorism epidemics; they become evident with the following classic syndromes:

- 1) *syndrome of changed reactivity* is represented by a higher rated of delicts and acts of terrorism, growth of multimodal tolerance and sadistic aggressiveness, impoverishment and exhaustion of the out of episode normative sociality;
- 2) *syndrome of psychic dependence* is represented by an obsessive attraction, mental comfort condition during a deviant and criminal situation, changed and perverted form of emotional experience towards delict or act of terrorism;
- 3) *syndrome of physical dependence* is represented by a compulsive attraction, composed of physical comfort during a deviant or criminogenic situation; changed and perverted forms of delict and terrorist act manifestation, “withdrawal syndrome”.

The syndromes of psychic and physical dependence determine the multi-episodic and compulsory nature of the epidemic generalization with asocial dependent behavior as well as the involuntariness of its appearance and difficulty in overcoming anomalous attraction of the commenced episode. They influence the degree of freedom when it comes to choosing a behavioral pattern. That is how they act as a psychopathologic foundation of possible dangerous serial actions [1]. Unfortunately, “Odessa’s Hatyn”, is just the beginning...

The growth of tolerance acts as a psychopathological foundation for the increased amount of aggressiveness and autoaggression, severity of repeated and serial delicts, acts of terrorism.

The out of episode dynamics of social terrorism epidemic shows itself in the form of growing destructive professiongenesis, emotional burnout and personality deformation, development of associated and comorbid psychosomatic disorders.

It is of principle importance to emphasize, that the *model of “synergetic individual”* allows to obtain a unified bio-psycho-socio-spiritual methodology of analysis for all epidemic forms of dependent disorders — ranging from alcoholism and drug abuse to fanaticism and terrorism, it corresponds to the high-priority directions of the mental medicine development [5].

6. MEDICAL-PSYCHO-SOCIO-SPIRITUAL DEFENCE FROM DESTRUCTIVE SOCIAL EPIDEMICS

The synergetic approach, that forms the foundation of mental medicine, presupposes a significant review of medical treatment, rehabilitation and preventive strategies of providing help to the dependent population and changing their ideology. The methodology of traditional socio-therapeutic and psychotherapeutic, socio-psychiatric and addiction relief services must be reviewed as well. Every dependent personality requires constant and interactive sanitization and correction that can only change the vector and modality of dependence.

When treating a dependent personality the main objective is to replace the modality of his dependence and change it from destructive to constructive, from non-adaptive to adaptive, from asocial to prosocial, from autoaggressive to self-preserving. This needs to be done at the earliest stage possible. The preventive strategy for treating dependent subpopulation requires adequate and regular loading of *adaptive socio-psychological and moral-spiritual content*.

On the basis of the synergetic concept of the destructive social epidemics development [11] we have elaborated a program of treatment and rehabilitation with preventive and correctional help. It represents a *unified multidisciplinary protocol* that is being implemented by a brigade of specialists. This program includes four blocks: medical, psychiatric, spiritual and moral, social (see table). These blocks are based on the four main types of ontogenesis planes (sociogenesis, psychogenesis, somatogenesis, and animogenesis) and are interconnected. All together they represent the synergetic methodology of mental medicine [10].

Medical block includes professional help of qualified psychiatrists,, narcologists,, general practitioners and physicians in frames of somatogenesis (ontogenetic development of the organism systems and functions).

Psychological block presupposes professional help of mental health specialists such as psychotherapists, clinical psychologists, psychiatrists in frames of psychogenesis (ontogenetic development of psychic functions).

Social help is provided in frames of sociogenesis (ontogenetic development of social roles and relationships) with the participation of social services (specialists in social work, social workers).

Spiritual and moral block animogenesis (ontogenetic spiritual and moral development of personality) this block is implemented with consultants and experts in ethics, clinical psychologists and general practitioners who know the peculiarities of the patient's family moral climate. Psychotherapeutic, educational and training methods together with the personal growth and coaching techniques block the syndromes of demoralization and destructive professiogenesis. When conflict situations emerge mediation on the basis of ethical committees is administered. Patients and clients get involved into development programs of different social organizations. This is how they consolidate the adaptive strategies of business communication ethics. The same objectives are reached when patients become participants of voluntary and social movements of paraprofessionals. They are needed in the rehabilitation programs for dependent people. Church-going patients may be effectively helped by spiritual mentors—representatives of official confessions.

Primary preventive measures should be taken in the *predisposition fractal*, where they can be used to determine hereditary and psychological predispositions as well as help with the psycho-psychological, spiritual and moral harmonization of the family relationship.

In the *latent fractal* special measures are taken to detect those individuals who are prone to organ neuroses. Attempts are made to correct the moral socialization of a personality as well as any psychopathic personality traits.

In the *initial fractal* when a non-pathological dependent behavior develops, special medicamental and psychiatric treatments are administered. This treatment prevents the development of dependent behavior and deformation of the moral make-up. In the fractal with *revealed clinical findings* early professional anti-addiction, psychotherapeutic, psychological, social, moral and spiritual help is required.

Table 5. Programme for medico-psycho-socio-spiritual help in social epidemics

Donosological fractals				Nosological fractals		
Blocks	Predispositions	Latent	Initial	Detailed clinical finding	Chronisation	Outcomes
Medical	Detection of people with hereditary predisposition, including them in the group of risk, early preventive examination	Detection of people with organ neuroses	Diagnostic of somatoform dysfunctions; medicamental and non-medicamental treatment	Detection of comorbid psychiatric diseases, prescribing medical therapy, prevention of complications	Adequate medicinal therapy of psycho-organic stigmatisation and psychosomatic diseases	Treatment for somato-neurological complications
Psychological	Detection of people with psychological load and taking preventive measures with them	Sanitation of psychopathisation of the personality	Detecting the dependent personality beyond personal disorder and correction of disorders	Correction of major personal disorders, psychotherapy.	Psychotherapy and psych-pharmacotherapy of dependent personality disorder	Psychological rehabilitation for psychiatric defect
Social	Detection and correction of violations of family structure and function	Correction of personality socialisation disorders	Correction of non-pathological dependent behaviour	Complex treatment of pathologically-dependent behaviour	Correction of social decompensation	Social rehabilitation
Morally-spiritual	Screening and correction of the family's "moral climate"	Correction of formation and development of moral feelings	Correction of formation and development of moral portrait	Reconstruction of moral positions	Reconstruction of moral behaviour	Morally-spiritual rehabilitation

Mental preventology

Clinical psychiatry

Mental medicine

In the *chronization fractal* adequate medicament therapy, psychotherapeutic treatment of the dependent disorder, socio-psychological, spiritual and moral corrections of the demoralization syndrome are administered regardless of the demoralization syndrome variant. These procedures are used with the alcohol demoralization syndrome as well as with the terroristic demoralization syndrome.

In those cases when there is a threat of *psychic defect or social dezadaptation* psychological, social, medical, moral and spiritual rehabilitations become necessary. They can be organized on the multidisciplinary basis with the help of the mental health service.

Mental health service – is a synergetic bio-psycho-socio-spiritual Ψ -cluster of society and state. It provides preventive and correctional protection of mental health and medical rehabilitation help for people with mental disorders.

The mental health service methodologically and technologically utilizes the resources of mental medicine, it creates a synergetic foundation that integrates classical clinical psychiatry, mental preventology (see table), makes it possible to organize a *systematic monitoring of mental health* and cardinally increases the efficiency social protection from destructive social epidemics. It is necessary to *reevaluate the mission of the prophylactic medical examination* (that are currently undergoing reforms) and conceptualize the systematic monitoring of the nation's social and mental health, expand the spectrum of its activity from narrow-specialized tactical tasks (infections, customer oriented, and others) *to strategic objectives that would create a social platform of national security*.

V. A. Medvedev [23] singled out the levels of motivation that give birth to terror and arranged them in a regressive sequence. This sequence shows the regression of generic and sociocultural nature and progression of individual personality components: biological (population), historic and cultural (mythological), ethno-psychological, group, individual psychopathology and sociopathy. The mirror reflection of these levels structures *the echelon system of antiterrorist defense*. All contemporary humanitarian counterterrorism models are based on the *systematic spiritual and ideological construction of national security that is founded on the life-forming meanings and moral values*.

The mental paradigm of national security includes: abatement of mental ailments consequences, strengthening of the nation's mental health; reduction of the spread of social destructive epidemics, self-destructive and dependent behavior, decrease of high mortality rates and social violence; lessening of the social stratification, poverty and unemployment; elimination of social vulnerability of seriously ill people and individuals with disabilities; overcoming of anomia and permissivity, deformation of social and individual consciousness, social isolation of an individual; formation of multivariant strategies of adaptive professiogenesis and effective self-management.

All preventive, correctional, therapeutic and rehabilitation measures of the bio-psycho-socio-spiritual programs, administered by the mental health service, must be inspired with the ideology of correction. The pessimistic and disastrous paradigm of world perception needs to be removed and replaced with the constructive life strategy that predetermines adaptive professiogenesis and stable development, prevention of endemic dependent disorders and spiritual immunity to destructive social epidemics.

Chapter 47

BULLYING INTERVENTIONS

Mary Ward Pollard, Courtney Walker and Janet W. Kwan

Mississippi State University, MS, US

ABSTRACT

Bullying has been defined as recurrent harassment of a student or group of students by another student or group. More specifically, bullying encompasses repeated negative actions with an intention to harm or disturb that involves a differential of power, where the more powerful individual attacks or harasses the individual who is less powerful individual. Studies have shown that bullying may lead to long-term negative effects, such as violence and depression, for the both perpetrator and the victim. Therefore, the development and examination of bullying interventions and their effectiveness is important in order to gain an understanding of which interventions may be the most effective in reducing bullying behavior. In general, school-based and/or whole-school approach to anti-bullying programs have been found to be the most empirically-supported intervention technique. However, other interventions, such as interventions aimed at changing the social norms around bullying behavior, have also been shown to be effective. The current chapter provides a thorough review of theoretically diverse bullying interventions that have been shown to be empirically effective at reducing bullying behaviors.

Bullying has been defined as the recurrent harassment of a student or group of students by another student or group. More specifically, bullying encompasses repeated negative actions with an intention to harm or disturb that involves a differential of power, where the more powerful individual attacks or harasses the individual who is a less powerful (Olweus, 1993). Bullying can occur in person, or over the Internet, as social media and other online outlets are becoming more and more popular. Internet bullying is more commonly referred to as “cyberbullying” and involves the use of primarily mobile phones and the Internet in the forms of text messaging, emailing, chatting, picture imaging, and social networking (Smith, 2011). Through these outlets, bullies can act in the forms of threats/intimidating, hacking/impersonation, manipulation/blackmail, and disclosing secrets (O’Higgins, Norman, & Connolly, 2011).

Studies have shown that there are long-term negative effects that result from bullying, such as violence and depression, for the both perpetrator and the victim (Ttofi, Farrington, & Losel, 2012; Ttofi, Farrington, Losel, & Loeber, 2011). One study examining the impact of bullying found that even when accounting and controlling for child psychiatric and family hardships, child victims of bullying were more likely to continue to have emotional problems in adulthood. Moreover, children who did not have pre-existing problems were also more likely to have later emotional problems if they were bullied (Copeland & Wolke, 2013). In addition, the behaviors that bullies utilize at school, both internalizing and externalizing, can be disruptive to the learning process and threaten the already limited teaching time that is available to both the teachers and the students (Paul, Smith, & Blumberg, 2012).

Studying interventions and their effectiveness is important to gain an understanding of which interventions have been shown to be the most effective in reducing bullying behaviors. Typically, bullying intervention and prevention efforts have focused on the school, targeting school policies, protocols, and procedures for responses to bullying incidents. School-based or whole-school approaches to anti-bullying programs have been found to be the most empirically supported intervention techniques (Ttofi & Farrington, 2012; Wurf, 2012). Generally, these methods consist of administrative elements such as anti-bullying policies, close monitoring, raising bullying awareness, curriculum activities and established management plans for incidents of reported bullying (Smith, Pepler, Rigby, 2004). Programs differ across schools, states, and countries; as such, program theories shift but can be loosely associated with theories regarding social learning, social development, and social interaction (Farrington & Ttofi, 2009).

Veeram and Carroll (2007) conducted a systematic review of school-based interventions to prevent bullying. Interventions were categorized into different types, such as curriculum (e.g., lectures), whole-school or multidisciplinary (e.g., teacher training, individual counseling), and social skills groups (e.g., group training in behavior modification). Of the different types of intervention, more whole-school approaches were found to directly reduce bullying more than other approaches (i.e., curriculum and social skills groups approaches; Veeram & Carroll, 2007).

Similarly, Ttofi and Farrington (2011) conducted a large-scale meta-analysis of 40 school-based anti-bullying programs across various countries. The results of the systematic review were congruent with the aforementioned systematic reviews. That is, results indicated that both bullying and victimization decreased as a result of a whole-school intervention program. Key elements such as intensity of the program (i.e., duration of children's participation and teachers' training), inclusion of parent meetings and firm disciplinary methods were found to be particularly effective (Ttofi & Farrington, 2011). In addition, the review also found school-wide anti-bullying policies, information for parents, improved playground supervision and classroom management were associated with decreased bullying. Further, Lee, Kim, and Kim (2013) conducted a meta-analysis of the effect of school-based anti-bullying programs. Findings emphasized that effective school-based interventions included training in emotional control, peer counseling, and a school policy on bullying. Taken together, these reviews provide convincing evidence for the investment, development, and implementation of school-based anti-bullying programs.

Other studies have examined what students perceive to be the most effective approaches to managing traditional bullying and cyberbullying. A study by Paul, Smith, and Blumberg (2012) measured various student perceptions of individual coping strategies and school interventions for bullying and cyberbullying and discovered that the highest intervention item ratings were

for School Sanctions and Disciplinary Action, primarily permanent suspension from school as the consequence for bullying or cyberbullying. Following behind student ratings for these two intervention items were the Informal Approach and Support Approach, and rated the lowest was the Curricular Approach. In Paul et al.'s 2012 study, results showed that students rated the support of family members, predominantly parents, to be the most helpful coping strategy.

In general, whole-school approaches to anti-bullying programs consist of combined support from the school, teachers, students, and parents in both prevention and intervention efforts (Smith, Pepler, & Ribgy, 2004). As mentioned before, these efforts often translate to administrative elements of intervention such as school-wide anti-bullying policies, close monitoring, raising bullying awareness, curriculum activities and established management plans for incidents of reported bullying (Smith, Pepler, & Ribgy, 2004; Wurf, 2012). Further, although intervention theories may vary amongst schools, states, and countries, most school-based programs have an underlying model that can be loosely associated with theories regarding social learning, social development, and social interaction (Farrington & Ttofi, 2009). This underscores the interpersonal aspect of anti-bullying intervention in promoting social skills and positive peer relations.

One particularly prevalent aspect of school-based approach intervention is the Shared Concern method (SCm; Pikas, 1989, 2002). It is a five-phase bullying intervention conducted by a teacher or counselor within a school setting. Adhering to a conflict resolution model, the intervention elicits non-punitive discussion with students involved and follow-up monitoring. The essence of this model stresses problem solving amongst the students involved, as opposed to traditional methods in which students are questioned, judged and punished (Rigby, 2005). In fact, many school-based programs within Farrington and Ttofi's (2011) meta-analysis consisted of this approach.

According to a recent study conducted by Wurf (2012) in which SCm is applied to four Hong Kong International Schools, the following are the five phases of the intervention. Phase one involves a one-on-one discussion with the student(s) suspected of bullying. Similarly, phase two consists of one-on-one discussions but with victimized student(s) to provide individuals with support and empathy for the situation. It is important to note this phase allows for the teacher or counselor to question whether the victim(s) provoked the bullies' behaviors. During phase three, another meeting is held with the student(s) who bullied to check their commitment to cease bullying behaviors. Then, phase four allows for the teacher or counselor to establish an agreement between both parties to prevent bullying. Lastly, phase five requires a follow-up to monitor whether bullying has ceased.

Importantly, the SCm has been found to be especially effective in bullying situations in which perpetrators consist of group involvement (Rigby, 2005). This is the case because it allows for a diffusion of responsibility such that the behavior of the group involved in bullying is addressed, as opposed to the behavior of one single perpetrator. In addition, this method emphasizes the importance of exploring group dynamics and individual motives for such behaviors.

In addition to the Shared Concern method, various other programs have been developed to target traditional bullying at school as whole-school approaches. The Bully Busters program was developed by Horne, Bortolomucci, and Newman-Carlson (2003) and provides teachers and administrators with ways to focus on raising awareness of the prevalence of bullying and to develop the essential skills for everyone involved at the school to deal with the problems that stem from bullying. Another focus of the Bully Busters program is to prevent bullying before

it starts by showing both students and faculty how to be proactive by acquiring skills, knowledge, and self-efficacy. In addition, there is a parental component that allows parents to learn what they can do to reduce incidence of aggression and bullying.

Whole-school approaches can also be implemented to target cyberbullying. As the use of technology in school-aged children is increasing, and will most likely continue to increase, it is important to target cyberbullying in interventions. Various studies have shown that evidence suggests most students who are cyberbullied are also bullied in other traditional ways (Beran & Li, 2007; Pearce, Cross, Monks, Waters, & Falconer, 2011). Therefore, it may be the case that strategies to address noncyberbullying behaviors, like the whole-school approach, may also effectively target cyberbullying behaviors (Pearce et al., 2011). Other current cyberbullying programs are centered on logical approaches and practical beliefs about prevention instead of scientific evidence (Snakenborg, Van Acker, & Gable, 2011). In these programs, schools implement various interventions, such as teaching students how to prevent bullying and how to effectively address instances in which they might become the victim or the bystander of an incident. In addition, some schools will introduce strategies to their students, such as cooperative learning, peer mediation, and social skills. In particular, some schools may especially focus on emphasizing these strategies to students who are deemed to be more at risk for becoming cyberbullying victims. These students may be anxious, withdrawn, insecure, physically weak, or smaller in size than other students (Snakenborg et al., 2011). However, these aforementioned strategies for addressing cyberbullying, both by itself and as a branch of more traditional bullying, are designed by individual schools and not based on scientific evidence. Researchers have been advocating for studies designed to investigate attributes of both bullies and their victims in order to develop more empirically based interventions (Wong-Lo, Bullock, & Gable, 2009).

Although the whole-school approach mainly targets interventions for bullying, and occasionally cyberbullying, once incidents occur, other approaches have been developed that aim to target bullying before it even happens. Traditionally, research has focused on individual factors (e.g., psychopathology) as well as contextual factors (e.g., socioeconomic status) as potential predictors of bullying behavior. Although this research has provided much insight as to what may contribute to a child engaging in bullying behavior, factors such as social norms and the perceptions of social norms also may play a significant role in bullying. Broadly, research on social norms and the perceptions of these norms has demonstrated that individuals have a tendency to conform to the social norms of his/her group (Asch, 1956). This may be particularly true for children and adolescents as their peers significantly influence their actions. For example, children who perceive bullying as a socially normative behavior amongst their peer group are more likely to engage in the behavior themselves than children who do not perceive bullying as a normative behavior amongst their peers (Duffy & Nesdale, 2008). This social influence on bullying is not exclusive to physical bullying; in fact, a youth's individual beliefs and perceptions of the presence of bullying in their school has also been shown to be predictive of relational aggressive behaviors (Elsaesser & Gorman-Smith, 2013).

It is also important to note that social influence has been found to play a role in bystanding behavior. Specifically, children who perceive that their classmates expect active interventions (e.g., telling a teacher) in bullying situations are less likely to engage in passive by standing behavior (e.g., not telling a teacher and allowing the bullying to continue). Interestingly, this effect on by standing behavior was not influenced by teacher expectations (i.e., perceiving that

the *teacher* expected the active intervention) and was stronger for children enrolled in middle school (Pozzoli, Gini, & Vieno, 2012).

These findings highlight the importance of social influence on bullying as well as by standing behavior. Overall, it would appear that if a child perceives bullying to be a socially abnormal behavior in his/her peer group or classroom, he/she might be less likely to engage in the behavior. In addition, if it is socially acceptable among a peer group to actively intervene in a bullying situation, a child may be more likely to intervene. This appears to be increasingly true for middle school aged children and may be due to the significant impact of social influence in their development. Specifically, adolescents may be more likely to adhere to their peer group's social norms in order to "fit-in." However, it is often the case that children and adolescents misperceive the actual norm of their school and communities. For example, a study observing health and well being in adolescents found that adolescents of a normal weight perceived themselves as being overweight and were more likely to experience a larger weight gain into young adulthood than those who did not have this misconception (Cuypers et al., 2012). In other words, adolescents held misconceptions of what constituted a normal weight and, as a result, were more likely to experience negative effects due to this belief. Thus, it may be that adolescents hold misconceptions about their peers' normative behaviors (e.g., high occurrences of bullying, few intervening behaviors) and that this misconception exacerbates the problem of bullying (Perkins, Craig, & Perkins, 2011). As such, interventions that attempt to alter perceptions of bullying as a socially normative behavior, as well as correct any misconceptions about the prevalence of bullying, may be more effective in reducing the behavior long term.

Perkins et al. (2011) developed a research intervention based on the premise that bullying is a function of conforming to peer norms as well as the perceptions of peer norms. The authors hypothesized that children who engage in bullying behavior may perceive that their peers are engaging in the behavior as well, thus conforming to a social norm. The authors also hypothesized that a misconception of the prevalence of bullying may actually exacerbate the bullying behavior. For the intervention, Perkins et al. (2011) obtained an initial baseline of students' perceptions of bullying. Next, the authors provided the students with feedback of the results of the survey in which conveyed the school's actual positive norms. An example of a norms message was, "most middle school students (9 out of 10) agree that students should always try to be friendly with students who are different from themselves" (Perkins et al., 2011).

Overall, Perkins et al. (2011) found that students' perceptions of the prevalence of bullying as well as peer support for bullying was widely misperceived. Specifically, students overestimated how often bullying occurred at their school and their peers' support for bullying. In addition, there was a positive association between students' perceptions of bullying as a supported and common behavior at their school and engaging in bullying behavior. Post-intervention scores indicated a statistically significant decrease in students' perceptions of bullying, self-reported victimization, and perceived peer support for bullying. Further, there was an increase in students' perceptions of peer willingness to report bullying to a teacher. In other words, it became more socially normative to report bullying behavior.

Also based on the notion that bullying may stem from social influences, Botvin, Mahalic, and Grotperter (1998) developed a program called "Life Skills Training." As a part of this program, school faculty help students in sixth- through ninth-grade to develop social skills in order to learn how to prevent violence, substance use and abuse, and other high-risk behaviors.

The students learn these social strategies by developing personal awareness about their own inter-and intrapersonal responsibilities and objectives.

Interventions aimed at changing the social normative beliefs about bullying, such as the intervention described above, may be effective in reducing bullying. In addition, these interventions also may be effective in making positive interventions (e.g., telling a teacher) a more socially normative behavior among a peer group. These interventions could be less likely to be susceptible to many of the barriers often observed with implementing a manual driven intervention into a school. Specifically, the intervention may not require a third party to train the school administration and teachers on how to implement the intervention and could also be freely available to schools. In addition, the intervention could be easily combined with an existing intervention program.

Although the various aforementioned programs have encompassed different focal points and goals, they all have a commonality in that they are universal interventions. In other words, the majority of the programs have been designed to target all students. However, there are also group interventions that focus on students who have demonstrated a high risk for bullying and/or aggression problems, both as instigators and victims. These group methods can take place in the classroom as a part of small group activities or counseling programs, and can coincide with teacher training groups as well that include support groups for maintaining and extending program activities as programs are implemented in their classrooms or with their students. The most common forms of group interventions are the psychoeducational groups, which are effective in assisting and guiding group members with issues they may have with adjustment, therefore possibly preventing future dysfunction (Home, Stoddard, & Bell, 2007). These psychoeducational groups can also help groups of normally functioning students by teaching fundamental skills in communicating respectfully and with empathy, building relationships with other students in the group, engaging in humor, and empowering each other, all while students practice teaching these skills to each other while minimizing outside discussion and promoting positive exchanges during group (Home, Stoddard, & Bell, 2007.).

Counseling groups are also used to target certain groups of students in the school setting. These groups can target more specific students than the psychoeducational groups, and spend more time addressing particular behaviors that the student(s) have previously demonstrated by examining and developing strategies to eliminate these negative bullying behaviors in the future (Home, Stoddard, & Bell, 2007). These groups typically spend more time on facilitating discussion with group members in order to discover the nature of their problems and allow for time to process emotional and cognitive content in order for the students to develop insight. Instead of teachers leading these counseling groups, typically, mental health professionals will offer guidance over these groups. For both psychoeducation groups and counseling groups, researchers have provided evidence that aggression-reduction focused group counseling may be as effective as individual counseling, which makes these interventions not only effective in reducing bullying behaviors, but also cost-effective (Schechtman, 2007).

The various interventions that are available to target bullying allow for schools to select an option that best fits their resources and theoretical orientation. Having multiple options also allow for adults to choose how they want to target bullying, in that they can select to prevent it through policies, educate students through discussions and literature, or appropriately punish to eliminate it. A critical first step in decreasing adolescent bullying is to become aware of the various interventions available and understand the empirical evidence of each intervention's effectiveness in different environments as depicted in scientific literature.

Abstract

Cyberbullying is widely recognised as a serious social menace which affects millions of people around the world, especially teenagers and adolescents. In this Chapter, we present the results of an online survey, which is conducted to understand and differentiate between real cyberbullying and cyberbullying-like instances in user-generated content. We study the subtle differences between the motives of the sender of messages similar to cyberbullying, and how messages are perceived by the recipient. In particular, we investigate forms, prevalence, and key indicators of cyberbullying within written contents. Firstly three variants of cyberbullying are introduced, namely: 'direct', 'indirect' and 'misinterpreted' forms of cyberbullying, based on the involvement of the recipient in these types of cyberbullying. Then we validate the key indicators which make written contents becomes cyberbullying, based on users' online experiences and the frequency with which they received and/or sent cyberbullying messages.

The findings reveal that: i) For direct cyberbullying, 'presence of loud language' and 'teasing - repeated comments or messages that may upset someone' are the main indicators in social networks. ii) For indirect cyberbullying, 'bullied or picked on by someone indirectly, as a third person, while online', 'been talked about online in ways that make you feel uncomfortable or upset', and 'been mentioned in a message to someone else in a way that is mocking or otherwise makes you feel uncomfortable or upset' are the main indicators. iii) For misinterpreted form of cyberbullying, 'bullied or picked on a friend or relative while online', 'been talked about online by a friend or relative, in ways that make you feel uncomfortable or upset' and 'been mentioned in a message to a friend or relative in a way that is mocking or otherwise makes you feel uncomfortable or upset' are the main indicators. These results are discussed in the light of the relatively limited cyberbullying detection research undertaken to date.

Keywords: cyberbullying, victimization, prevalence, social networks, cyberbullying indicators

1. Introduction

This study is driven by an urgent need for the early detection of cyberbullying activities in social networks. Recently, a public row broke out when seemingly private messages of an Indian Union minister were published on his Twitter feed, which resulted in tragic suicide of his wife. He is a former U.N. diplomat, a prolific author, and one of the most active users of the microblogging site in government, whose Twitter account shows more than 2 million followers. In another case, an Australian top model committed suicide on 21 February, 2014 because of cyberbullying. Therefore, more generalised opinion of online community's who either experienced or were involved in cyberbullying needs further investigation.

Cyberbullying is defined as "an act of posting cruel or harmful material to others or engaging in other forms of social aggression using the Internet or other communication technologies" [1]. Though cyberbullying is a common phenomenon among adolescents and children, breakthrough advancements in information and web-based technologies, such as social networking sites, straddle age groups, where non-physical aggression is often observed among different age group users. Research conducted in various countries, including Serbia, the UK, the USA, Korea, Turkey, Italy, and Australia clearly indicate that nearly 90% of school-aged students access the Internet at home, with over 50% reporting daily use [2–4], which they use to interact in cyber space. Teachers and administrators have recognized student's use of information and communication technology, particularly in their social interaction via the expanding use of electronic communication in school classrooms [5, 6]. World-wide, studies reveal that most school-aged students now own a mobile phone and this increases with age [2]. An empirical study conducted by Aricak (2009) in the Turkish environment reveals the fact that ease of maintaining anonymity in cyberspace is one of the most significant causes of cyberbullying [7]. He also found that males are more likely than females to validate that they would engage in cyberbullying in the future. Furthermore, this study also suggests that cyberbullying is not limited to children and adolescents, but extends to adults as well.

The very act of a bullying activity is harmful in some way or the other and its implication are so dangerous that it may destroy the precious lives of youths when they fail to cope with the unbearable pressure of insulting or humiliating messages, especially on the Internet, where the potential audience of cyberbullying is limitless [8]. In such settings, it is beneficial to have an automatic system which can monitor such harmful messages and alert users of its repetitive occurrence. This will help to maintain a safe and healthy online environment for all users and confirms there is a need for detection software.

In the view of the facts that: (i) Young people have seized the Internet as both an option and a means for socializing [1] such as Social Networking sites; (ii) There is increasing evidence of the existence of cyberbullying, including situations where the outcome has been suicide; (iii) Bullying in cyberspace is a difficult occurrence for parents or guardians to monitor young children/students' actions [9]; (iv) Young people (especially teenagers) are reluctant to tell adults about incidents where they are being bullied, whether in real life or cyberspace. In addition, only a few participants use appropriate means to prevent incidents

Cyberbullying Validation 803

of online bullying [10]. This chapter aims to study the online user's comprehension of the existence and frequency of cyberbullying. The study is based on the frequency of received and sent messages under varying conditions, including participation in direct, indirect and the misinterpreted forms of cyberbullying. In addition, this study explores the cyberbullying indicators in user-generated content that can be utilised for the detection of cyberbullying on social networks [11--22].

Though cyberbullying is a problem that gets a lot of attention from a Social Science point of view, less attention has been paid to it from an automatic detection angle. A number of definitions of cyberbullying, revealing the principal characteristics of cyberbullying are: an imbalance of power, repetitive patterns, intentional hurt, and where a victim is unable to defend him or herself.

To differentiate between cyberbullying and cyber teasing requires understanding the subjective difference between the way a message is intended in relation to how it is perceived. As a result, automatic detection becomes an important research challenge. The aim of this study is to establish a number of rules that can be included in cyberbullying detection tools. Rules will be established based on the frequency of potentially offending messages and the patterns of communication between online users taking part in harassing/cruel or threatening/unpleasant messaging. In this chapter, we examine a number of indicators in user-generated content which identify the online content as apparently of a bullying nature. We look at the frequency of offensive or hurtful messages being sent and received as a basis to predict the communication pattern of intentionally hurtful acts.

Based on the above-mentioned literature, previous compiled research into the characteristics of cyberbullying, and profiles of cyber bullies; this chapter will take the following into account:

First, the demographic characteristics (gender, age and religion) of the Internet users, who have involved or experienced cyberbullying will be studied. Second, indicators of direct cyberbullying and the frequency where users see themselves engaged as a bully, or a victim, of a direct form of cyberbullying will be included in the analysis. Third, indicators of indirect cyberbullying and the user's engagement based on the frequency in indirect cyberbullying will be examined. Forth, indicators of misinterpreted form of bullying, and the frequency of the misinterpreted form of bullying (cyberbullying-like posts or messages between close friends or people in close a relationship) will be explored.

2. Methodology

2.1. Participants and settings

The study focuses on obtaining feedback on the nature and prevalence of cyberbullying from the Internet users of different age groups and genders, based on the frequency of offensive posts received. Consequently, in this study, an anonymous online survey via SurveyMonkey was conducted through Social Media websites (Twitter and Facebook). A link to the questionnaire was distributed on social networks including Twitter and Facebook, and participants were randomly invited to complete it.

Voluntary participants included but were not limited to students/staff/members of the University of Queensland (UQ) community. Students, academics and research peers were

804 Vinita Nahar, Xue Li and Chaoyi Pang

also approached to fill out the online questionnaire. Although not specifically targeted, people from communities outside of the UQ have also participated. As a strategy to obtain informed consent, it was requested that people under 18 years seek the permission from a parent or guardian before participating in the survey. Prior to the research being conducted, the study had been cleared in accordance with the ethical review processes of the University of Queensland, Australia.

2.2. Procedure

To closely investigate the amount of cyberbullying and cyber harassment, we chose groups in various age ranges (12-17 years, 18-21 years, 22-25 years, 25-30 years) and grouped users above 30 years as a single entity. In addition, we made the assumption that these Internet users had Social Network accounts on Twitter and Facebook. The questionnaire was separated into five parts:

Part A: Relating to demographic factors;

Part B: Relating to direct cyberbullying;

Part C: Relating to indirect cyberbullying;

Part D: Relating to misinterpreted form of cyberbullying;

Part E: General questions about cyberbullying.

The pilot survey was carried out by interviewing a few UQ students and academics.

After this, modifications were made based on the feedback and the revised questionnaire was posted on the SurveyMonkey website.

A filter question (Have you experienced or been involved in cyberbullying?) was used to filter out participants who have never been involved in, nor experienced cyberbullying. To determine the best indicators of direct, indirect and misinterpreted forms of cyberbullying; the definitions of these types of cyberbullying were provided explicitly. Additionally, indicators were prepared for each type of cyberbullying independently.

Respondents were asked to respond to each question regarding what constitutes cyberbullying, and the number of times they have experienced or been involved in any of the three types of cyberbullying. The statistical analysis of all the data was done by computing the Cronbach's alpha, the Spearman's Correlation Coefficient, Linear Regression Analysis and the Coefficient of determination using SPSS. Significance was calculated both 5% and 1% levels.

2.2.1. Demographic Factors

Participants were asked for their age, gender and religious background in order to study their profile, which constitutes Part A of the questionnaire.

Cyberbullying is defined as "an aggressive, intentional act carried out by a group or individual, using electronic forms of contact, repeatedly and over time against a victim who cannot easily defend him or herself" [23]. After giving this definition, four indicators - 'appearance of bad words in messages such as insults, e.g., fool, or crude words, e.g., bitch', 'direct use of bad words to describe someone, e.g., You are a fool', 'presence of

Cyberbullying Validation 805

loud language, foul words, names written in capital letters making it obvious in a message, e.g., 'You FOOL!!', and 'teasing' - repeated comments or messages that may upset someone, were examined to measure what constitutes cyberbullying on the Likert six-point scale from 'Strongly agree' (scale level - 5) to 'Not applicable' (scale level - 0). Another Likert six-point scale from 'Every day' (scale level - 5) to 'Never' (scale level - 0) was constructed to measure their experiences and involvement with cyberbullying in Part B of the questionnaire. The participants were asked how frequently they had been involved in cyberbullying as a victim or as a bully by explaining their experience using eleven indicators.

For the bully, the indicators included: 'bullied or picked on someone online', 'sent or posted offensive message to others', 'sent or posted a secret message to someone and that person was upset about this', 'sent a message online, which mocked the receiver or otherwise upset them' and 'sent an offensive message online to a friend or relative'. For victims, indicators included: 'been bullied or picked on by someone, or a group, online', 'received offensive message from others', 'been frightened to go online', 'received a message that you did not want others to see', 'received a message online, which mocked you or otherwise upset you' and 'received an offensive message online from a friend or relative'.

2.2.2. Indirect Cyberbullying

In Part C of the questionnaire, a model for 'indirect cyberbullying' was created. The definition of indirect bullying was defined as 'the presence of bad words in a message in association with the third person pronoun (i.e., 'he', 'she' etc.) e.g., He is a fool'. Then, to measure participants' experience with indirect cyberbullying, they were asked how often they had experienced or been involved with indirect cyberbullying, using the Likert six-point scale from the 'Every day' (scale level - 5) basis to the 'Never' (scale level - 0).

Another Likert six-point scale from 'Every day' (scale level - 5) to 'No cyberbullying' (scale level - 0) was developed to measure their engagement as a victim or as a bully in indirect cyberbullying, based on the five points scale. The indicators for the bully are: 'talked about others, in ways that would make them feel uncomfortable or upset', and 'mentioned someone in a message to a third party in a way that was mocking or otherwise makes them feel uncomfortable or upset'. For the victim, indicators include: 'bullied or picked on by someone indirectly, as a third person, while online', 'been talked about online in ways that make you feel uncomfortable or upset' and 'been mentioned in a message to someone else in a way that is mocking or otherwise makes you feel uncomfortable or upset'.

2.2.3. Misinterpreted Form of Cyberbullying

The fourth model (Part D) is defined as a 'misinterpreted form' of cyberbullying, which is introduced in the questionnaire to understand the difference between cyberbullying and cyber-teasing. A misinterpreted form of cyberbullying is defined as 'the harassing or rude behaviour that appears between close friends or in close relationships'. Close friends may often use coarse or rude language without intending to hurt/insult/upset each another, for example simply cracking a joke may sometimes be seen as an insult. To measure misinterpreted form of cyberbullying and bullying behaviour, instances within close relationships and friendships were carefully examined. Two questions similar to those used for indirect cyberbullying were constructed on the same scale. In addition, to understand the reaction

806 Vinita Nahar, Xue Li and Chaoyi Pang

of the receiver of bullying-like message online, a new question is added. Respondents indicated their reaction through multiple-choice options: 'took it seriously and replied with a bullying message', 'took it seriously and never replied', 'didn't take it seriously and replied in a normal way', 'didn't take it seriously and ignored it' and 'other - please specify'. Another Likert six-point scale from 'Every day' (scale level - 5) to 'No cyberbullying' (scale level - 0) is developed to measure their engagement as a victim or as a bully in misinterpreted form of cyberbullying, based on the five points scale. The indicators for misinterpreted form of cyberbullying are: 'talked about a friend or relative, in ways that would make them feel uncomfortable or upset', and 'mentioned by a friend or relative in a message in a way that was mocking or otherwise makes them feel uncomfortable or upset'. While for the victim, indicators include: 'bullied or picked up by a friend or relative, while online', 'been talked about online by a friend or relative, in ways that make you feel uncomfortable or upset', and 'mentioned by a friend or relative in a message in a way that was mocking or otherwise makes them feel uncomfortable or upset'.

2.2.4. General Questions about Cyberbullying

In Part E, three multiple-choice questions were developed regarding the general questions about cyberbullying, such as main sources of cyberbullying, motives of cyberbullying, and participants' reactions to cyberbullying messages. A question to measure the level of severity of cyberbullying based on the percentage of cyberbullying was developed. Four severity levels were defined including 'Severe', 'Moderate', 'Normal', and 'Non-bullying'. Participants were also asked to provide five unusual bullying words they have encountered for the first time.

3. Results and Discussions

This study into cyberbullying among Internet users explored the phenomenon of cyberbullying from the perspective of identification of the indicators of cyberbullying in user-generated content. In this study, the prevalence of cyberbullying is investigated only from the respondents who have experienced or been involved in cyberbullying.

3.1. Demographic Details

Figure 1 shows the percentage distribution of participants based on gender. Of those who took part in the study, a total of 53.4% female, 42.7% male, and 3.9% of respondents did not mention their gender. We can note that the female participation is slightly higher than males. Nevertheless, the study was consistent to obtain almost equal opinions of male and female online users of their cyberbullying experiences.

The age is divided into five groups: 12-17 years, 18-21 years, 22-25 years, 26-30 years and 30 years plus. As shown in Figure 2, out of the total participants, 27.3% belong to the age group 12-17 years, which is the highest percentage, followed by 24.1% users aged over 30 years, 19.0% of 18-21 years group, 16.8% people of 26-30 years, 11.9% users fall in to the 22-25 years of age group and 1% of users didn't reveal their age. For our study, we can also conclude that people over 30 years are almost equal in number that those who

are between 12-17 years old. This shows that not only teenagers and young children are users on social networking sites, but elder group of people are also frequent users of these websites. This is in line with our intuition that with the proliferation of social networks, people of all ages are being affected by online bullying and abuse.

**Correlation is significant at the 0.01 level (2-tailed)

Table 3 shows that during the last month, teenagers were most frequently involved in cyberbullying or targeted by cyberbullies (52.4%), compared to other groups. The frequency of the involvement of people of other age groups is lower in the previous month compared to the previous two months. Also, we can observe that the frequency of the involvement decreases as age increases. It shows that teenagers are the most involved group, whereas

810 Vinita Nahar, Xue Li and Chaoyi Pang
the least involved people are over 30 years old. We can see that involvement in cyberbullying activity is decreasing with the age, and there is an immediate need to spread awareness among teens.

Table 4. Correlation between involvement or experience of cyberbullying and frequency of cyberbullying (Q6&Q7)

As shown in Table 4, the correlation coefficient between experience or involvement of cyberbullying and last time involvement in cyberbullying is highly significant at the 0.01 level (2-tailed), which shows a strong relationship existed between these two variables.

3.2. Direct Cyberbullying

The internal reliability of the four indicators of Q8 and the eleven indicators of Q9 and experience or involvement of cyberbullying (Q6) is calculated by using Cronbach's alpha. The overall alpha coefficient is 0.953 (range if one item deleted, from 0.958 to 0.946), suggesting excellent reliability.

3.2.1. Involvement or Experience of Cyberbullying and Indicators of Direct Cyberbullying (Q6 & Q8)

Participants were asked what constitutes direct cyberbullying, by providing the list of four indicators: 'appearance of bad words in messages', 'direct use of bad words to describe someone', 'presence of loud language' and 'teasing - repeated comments or messages that may upset someone'. In addition, five options from 'strongly agree' (scale level - 5) to 'not applicable' (scale level - 0) were given in the questionnaire. The 'strongly agree' indicators (at scale level - 5) proving to be most common were the 'teasing - repeated comments or messages that may upset someone' (56.8%) and 'presence of loud language' (48.7%). Furthermore, 'direct use of bad words to describe someone' (63.2%) and 'appearance of bad words in messages' (51.3%) were the most frequent 'agree' items (at scale level - 4). It is important to note that none of the respondents answered 'Not applicable' for any of these four items, while less than 2% of the respondents marked the occurrences of these indicators as 'strongly disagree' as a sign of cyberbullying. This demonstrates that the four given points are good indicators to identifying online bullying content. Nevertheless, the 'presence of loud (capitalised) language' and 'teasing' are more prominent than the 'appearance of bad words' and the 'direct use of bad words' to describe the constitution of cyberbullying. The detailed table is given in Appendix II.

**Correlation is significant at the 0.01 level (2-tailed)

*Correlation is significant at the 0.05 level (2-tailed)

The experience and involvement in cyberbullying is a dichotomous variable coded 1

if the respondent answered 'Yes', 2 if a respondent answered 'No'. As shown in Table 5,

the correlation coefficient between experience of, or involvement in cyberbullying, and the

'appearance of bad words in messages, such as insults', 'presence of loud language' and

'teasing' is 'highly significant' at the 0.01 level (2-tailed), which shows a strong relationship

existed. Whereas, significant for 'direct use of bad words to describe someone' at the 0.05

level (2-tailed). However, linear regression analysis between the dependent variable (expe-

rience of or involvement in cyberbullying) and independent variables (as given in Table 5

from serial letters 'a' to 'd') suggests that the coefficients of determination (R^2) between

involvement in or experience of cyberbullying, and 'Presence of loud language' and 'Teas-

ing' are 12.7% and 10.9% respectively. This means these independent variables accounted

for 12.7% and 10.9% of the total variation in the dependent variable i.e., involvement in or

experience of cyberbullying. These two independent variables are the main indicators of

direct cyberbullying, whereas the R^2 between involvement or experience of cyberbullying

and all the four indicators of Q8 is 15.6% as shown in Table 6.

3.2.2. Involvement or Experience of Direct Cyberbullying and its Frequency

(Q6 & Q9)

Given the list of eleven cyberbullying examples, participants were asked the frequency on

a scale from 'Every day' to 'Never' by which they have been bullied or have bullied others.

The majority of participants agreed on the 'A few times' option as they 'had received an

offensive message' (41.0%), 'they had received a message online which mocked or upset

them' (40.4%), 'had received a message that they did not want others to see' (39.9%), 'had

been bullied or picked on by someone or a group online' (37.0%), 'they felt frightened to go

online' (35.4%), and 'they received an offensive online message from a friend or relative'

(34.8%). Furthermore, the majority of the respondents (43.8%) said that they never sent a

message online which mocked the receiver or otherwise upset them. The detailed table is

given in Appendix III.

On one hand, around 50% people said that they have received cyberbullying messages,

while on the other hand fewer than 10% of people accepted that they have ever sent bullying

messages. This opens up a new direction of research to discover if people are ignoring

the fact they are bullying others; or if they have done it unknowingly. Here we can see

that there is a huge gap between intentional cyberbullying and unintentional cyberbullying.

Nevertheless, whatever the case is, around 50.0% of people accepted that they felt bad on

receiving a message of an apparently cyberbullying nature.

The internal reliability of Q10 and the five indicators of Q11 and experience of or involvement in cyberbullying (Q6) is calculated by using Cronbach's alpha. The overall alpha coefficient is 0.940 (range if one item deleted, from 0.922 to 0.951), suggesting excellent reliability. Given a model for 'Indirect cyberbullying', which includes a series of indirect cyberbullying examples, respondents were asked the frequency by which they had been involved in or experienced indirect cyberbullying on the scale of 'Every day' to 'No cyberbullying'. The majority of people accepted that 'A few times' they have 'been talked about online, in ways that make you feel uncomfortable or upset' (39.2%), 'been mentioned in a message to someone else in a way that is mocking or otherwise makes you feel

816 Vinita Nahar, Xue Li and Chaoyi Pang
uncomfortable or upset' (38.8%), and 'bullied or picked up by someone indirectly, as a third person, while online' (35.4%). These three items are identified as the most common examples for the involvement in indirect cyberbullying activities. In addition, nearly the same percentage of respondents said that they have not bullied others in any of these ways. This also suggests that the majority of victims of indirect cyberbullying did not indirectly cyberbully others. These findings are in line with the direct versus indirect measurement of cyberbullying [10], where indirect measures includes the experience of youngsters with traditional bullying, and their Information and Communication Technology's (ICTs) use was measured in order to situate cyberbullying within these youngsters' lives. Their findings suggested that 61.9% of respondents had been victims, 52.5% had been perpetrators, and 76.3% had been bystanders to at least one POP (potentially offensive Internet and mobile phone practice). The detailed table is given in Appendix IV.

*Significant at p # 0.05								

The experience and involvement in cyberbullying is a dichotomous variable coded 1 if the respondent answered 'Yes', 2 if a respondent answered 'No'. As shown in Table 9, the correlation coefficient between experience of or involvement in cyberbullying and all the indicators of indirect cyberbullying is highly significant at the 0.01 level (2-tailed), which shows a strong relationship existed. However, linear regression analysis between the dependent variable (experience of or involvement in cyberbullying) and independent variables (as given in Table 9 from serial letters 'a' to 'e') suggests that the coefficients of determination (R 2), between involvement or experience of cyberbullying and 'been mentioned in a message to someone else in a way that is mocking or otherwise makes you feel uncomfortable or upset', 'bullied or picked on by someone indirectly, as a third person, while online', and 'been talked about online, in ways that make you feel uncomfortable or upset', is 40.6%, 38.7%, and 37.6% respectively. This means these independent variables accounted for

Cyberbullying Validation 817

40.6%, 38.7%, and 37.6% of the total variation in the dependent variables i.e., involvement or experience of cyberbullying. These three independent variables are the main examples of indirect cyberbullying based on frequency, whereas the R² between involvement in or experience of cyberbullying and all the five indicators of Q11 is 45.4%, as shown in Table 10.

The internal reliability of Q12 and the five indicators of Q13, and experience of or involvement in cyberbullying (Q6) is calculated by using Cronbach's alpha. The overall alpha coefficient is 0.927 (range if one item deleted, from 0.903 to 0.933), suggesting excellent reliability.

A list of five items and the frequency scale from 'Every day' to 'No cyberbullying' were given for the 'misinterpreted form' of cyberbullying model. Participants were asked the frequency by which they had been involved in or experienced misinterpreted form of cyberbullying on the scale of 'Every day' to 'No cyberbullying'. Of the total, 38.2%, 37.3%, and 36.5% respondents opted 'No cyberbullying' for the 'bullied or picked up by a friend or relative, while online', 'talked about a friend or relative, in ways that would make them feel uncomfortable or upset', and 'mentioned by a friend or relative in a message in a way that was mocking or otherwise makes them feel uncomfortable or upset', respectively. The majority of people accepted that 'A few times' they have 'been talked about online by a friend or relative, in ways that make you feel uncomfortable or upset.' (36.9%), and 'been mentioned in a message to a friend or relative in a way that is mocking or otherwise makes you feel uncomfortable or upset.' (34.8%), and 'bullied or picked up by a friend or relative, while online' (33.1%). These three items are identified as the most common examples for

818 Vinita Nahar, Xue Li and Chaoyi Pang

the involvement in misinterpreted form of cyberbullying activities. In addition, nearly the same percentage of respondents said that they have not bullied others in any of these ways. This also suggests that the majority of victims of misinterpreted form of bullying did not bully others in the same way. The detailed table is given in Appendix V.

Table 12. Regression (stepwise) analysis, model summary (Q12 & Q13)

a. Dependent Variable: Have you experienced or been involved in cyberbullying?							
N=422							
**Significant at p # 0#01							
*Significant at p # 0#05							

The experience of and involvement in cyberbullying is a dichotomous variable coded 1 if the respondent answered 'Yes', 2 if a respondent answered 'No'. As shown in Table 11, the correlation coefficient between experience of or involvement in cyberbullying and all the indicators of misinterpreted form of cyberbullying is highly significant at the 0.01 level (2-tailed), which shows a strong relationship existed. However, linear regression analysis between dependent variables (experience of or involvement in cyberbullying) and independent variables (as given in Table 5.10 from serial letters 'a' to 'e) suggests that the coefficient of determination (R 2), between involvement in or experience of cyberbullying and being 'been mentioned in a message to a friend or relative in a way that is mocking or otherwise makes you feel uncomfortable or upset', 'bullied or picked up on a friend or relative, while online', and 'been talked about online by a friend or relative, in ways that make you feel uncomfortable or upset' is 43.6%, 43.4%, and 42.2% and respectively. This means these independent variables accounted for 43.6%, 43.4%, and 42.2% of the total variation in the dependent variable i.e., involvement in or experience of cyberbullying. These three independent variables are the main indicators of misinterpreted form of cyberbullying based on frequency, whereas the R 2 between involvement or experience of cyberbullying and all the five indicators of Q13 is 47.7%, as shown in Table 12.

Research demonstrates that the differentiation between cyberbullying and cyber-teasing depends on the subjective difference between the ways messages were intended versus how

Cyberbullying Validation 819

they were perceived. Given that the use of coarse or rude language is often a common phenomenon among close friends or those in close relationships, without intent to hurt each other. Of the total, 43% of respondents agreed that they had experienced this type of bullying behaviour 'A few times'.

Therefore, participants were asked for their reaction while experiencing this behaviour, through multiple-choice questions. Of the total, 44.4% of respondents said that they 'took it seriously and replied with a bullying message', and 46.3% mentioned that they 'took it seriously and never replied'. Here, based on the frequency, we formed a rule by computing the likelihood of the given rude or hurtful messages, m , sent between friends, so the probability that m is cyberbullying ($y = 1$) or not ($y = -1$) can be defined as:

$$y = X(m \# f); y \# \{1, -1\} \quad (1)$$

$$y = \# 1 \text{ if } 0 \# 06 < f < 0 \# 23;$$

$$-1 \text{ if } 0 \# 23 \# f \# 1 \text{ or } 0 \# 0 \# f \# 0 \# 06$$

(2)

where, f is the frequency of the hurtful message over the total number of messages, over a period of one month ($n = 30$), and range of f is given as $0 \# f \# 1$.

This demonstrates that people ignore rude or coarse behaviour between close friends or in close relationships for 'A few times', but as the frequency of such occurrences increases, it may result in more serious cases of cyberbullying and not just jokes or intentional acts of poking fun at a friend. Similarly, it is also not classified as cyberbullying if it happens so frequently that it can be considered as the usual way of communication between two good friends who have a mutual understanding of the comments made. However, unusual patterns can indicate that there is something wrong and the behaviour could be an intentional act to hurt a friend. Also research demonstrates that cyberbullying victimisation is more frequent among peer groups [24].

These inconsistent results clearly indicate that not all online variants of cyberbullying (or what appears to be cyberbullying) are considered as real cyberbullying cases [25]. It is a matter of perception of the message sender as well as the message recipient whether they consider the message or behaviour as 'funny' or 'hurtful' [25]. Similarly, findings from the study regarding cyberbullying behaviours of teenagers from different socio-economic backgrounds among public and private school students revealed that participants from private schools did not mind cyberbullying because they thought it was a joke, whereas participants from public schools reported that they felt angry when faced with cyberbullying [26].

Conclusion

With regards to the prevalence of cyberbullying in social networks, the following observation seems to be especially relevant in light of the development of the cyberbullying indicators from the user-generated content: For direct cyberbullying, 'presence of loud language' and 'teasing - repeated comments or messages that may upset someone' are the main indicators in social networks. For indirect cyberbullying, 'bullied or picked on by someone indirectly, as a third person, while online', 'been talked about online, in ways that make you feel uncomfortable or upset', and 'been mentioned in a message to someone else in a way that is mocking or otherwise makes you feel uncomfortable or upset' are the main

820 Vinita Nahar, Xue Li and Chaoyi Pang

indicators. For misinterpreted form of cyberbullying, 'bullied or picked up on a friend or relative, while online', 'been talked about online by a friend or relative, in ways that make you feel uncomfortable or upset' and 'been mentioned in a message to a friend or relative in a way that is mocking or otherwise makes you feel uncomfortable or upset' are the main indicators.

Abstract

Nowadays, cyberbullying is becoming an increasingly obvious concern, especially among children and teenagers. Cyberbullying can have an extremely negative impact on victims and in the worst scenarios, it can actually result in suicidal attempts. In this Chapter, we present the results of an online survey, which is conducted to study the sources, motives and reaction to cyberbullying. The study focuses on obtaining feedback on the nature and prevalence of cyberbullying from the Internet users of different age groups and genders, based on the frequency of offensive posts received. Findings reveal that in social networking websites, instance messaging and chat rooms are the main sources of cyberbullying. Items 'to show hate', 'to make fun of someone', and 'to copycat others in cyberbullying activities' are the main motives of cyberbullying. The main reactions to cyberbullying are 'replied in a bullying manner', 'never replied' and 'blocked someone'. To differentiate real bullying from cyberbullying-like or non-bullying messages, the frequency between sender and receiver over a long period of a time can be seen to demonstrate whether it is an unusual (intentional) act of teasing, or a usual (unintentional) act that generally exists between good friends or those in close relationships. However, it is important to note that a frequent pattern should not be confused with frequent coarse language at one particular time. The unusual patterns over a long period of time should be considered as clear indicators of true bullying.

1. Introduction

Though cyberbullying is a common phenomenon among adolescents and children, breakthrough advancements in information and web-based technologies, such as social networking sites, straddle age groups where non-physical aggression is often observed among different age group users. Research conducted in various countries, including Serbia, the UK, the USA, Korea, Turkey, Italy, and Australia clearly indicate that nearly 90% of school-aged students access the Internet at home, with over 50% reporting daily use [1–4], which they use to interact in cyberspace. Teachers and administrators have recognized students' use of information and communication technology, particularly in their social interaction via the expanding use of electronic communication in school classrooms [5,6]. Worldwide, studies reveal that most school-aged students now own a mobile phone and this increases with age [1, 2]. An empirical study conducted by Aricak [7] in the Turkish environment reveals the fact that ease of maintaining anonymity in cyberspace is one of the most significant causes of cyberbullying. He also found that males are more likely than females to validate that they would engage in cyberbullying in the future. Furthermore, this study also suggests that cyberbullying is not limited to children and adolescents, but extends to adults as well.

The very act of a bullying activity is harmful in some way or the other and its implications are so dangerous that it may destroy the precious lives of youths when they fail to cope with the unbearable pressure of insulting or humiliating messages, especially on the Internet, where the potential audience of cyberbullying is limitless [8]. In such settings, it is beneficial to have an automatic system which can monitor such harmful messages and alert users of its repetitive occurrence. This will help to maintain a safe and healthy online environment for all users and endorses the need for detection software.

In light of the facts that (i) young people have fully embraced the Internet as both an environment and a tool for socialising [9] on place like social networks; (ii) there is growing evidence of the existence of cyberbullying, including cases which have resulted in suicide; (iii) bullying in virtual reality is a difficult phenomenon for adults to monitor young children/students' actions [10]; (iv) young people (especially teenagers) do not tell adults about cyberbullying incidents and only a minority of participants use digital tools to prevent online bullying incidents [11]. This chapter aims to study the online users' understanding of the prevalence of cyberbullying.

Based on the frequency of sent and received messages under various conditions, such as involvement in direct, indirect and the misinterpreted form of cyberbullying, this chapter investigates the cyberbullying indicators in user-generated content that can be used towards cyberbullying detection in social networks. While cyberbullying is a problem that receives a lot of attention from the social science perspective, it has received much less research attention from the automatic detection perspective. Various definitions of cyberbullying, revealing the attributes which are inherent in the act of cyberbullying are: intentional hurt, repetitive patterns, an imbalance of power, and where a victim is unable to defend him/herself.

The differentiation between cyberbullying and cyber-teasing depends on the subjective difference between the ways messages were intended versus how they were perceived, and as a consequence automatic detection poses an important research challenge. The aim of

Cyberbullying Prevalence - Medium, Motive and Reaction 825

this study is to develop rules, which can be incorporated within cyberbullying detection tools. Rules will be based on the frequency of offensive messages and the communication patterns between online users engaging in harassing/cruel or offensive messaging. In this chapter, we study various indicators in user-generated content which makes the online content appear as bullying content. We consider the frequency by which offensive or hurtful messages are sent and received as a basis to predict the communication pattern of an intentionally hurtful act.

As a part of this research, we conducted an online survey where we examined users understanding on how they consider cyberbullying-like posts as real-cyberbullying or non-cyberbullying. Previous investigations have been conducted based on the formal definitions of cyberbullying, indicators of cyberbullying, opinions of the people who are actually involved in or who have experienced cyberbullying, and their reactions to the cyberbullying incidents. Based on the above-mentioned literature relating to the prevalence of cyberbullying and involvement of the Internet users in cyberbullying activities, the current studies sources and causes of cyberbullying as well as the reaction to cyberbullying.

2. Methodology

2.1. Participants and Settings

The study focuses on obtaining feedback on the nature and prevalence of cyberbullying from the Internet users of different age groups and genders, based on the frequency of offensive posts received. Therefore, in this study, an anonymous online survey via SurveyMonkey 1 was conducted through social networks. A link to the questionnaire was distributed on social networks including Twitter and Facebook, and participants were randomly invited to take part.

Voluntary participants included, but were not limited to, students/staff/members of the University of Queensland (UQ) community. Students, academics and research peers were also approached to fill out the online questionnaire. Although not specifically targeted, people from communities outside of the UQ have also participated. As a strategy to obtain informed consent, it was requested that people under 18 years seek the permission from a parent or guardian before participating in the survey. Prior to the research being conducted, the study had been cleared in accordance with the ethical review processes of the University of Queensland, Australia.

2.2. Procedure

To examine the extent of cyberbullying and cyber-harassment, we selected different age groups (12-17 years, 18-21 years, 22-25 years, 25-30 years) and grouped users above 30 years as a single entity. In addition, we assumed that these Internet users have accounts on social networks such as Facebook and Twitter, which are the most popular social networks, and the mode through which the survey was conducted. The questionnaire was divided into five parts:

1 <http://www.surveymonkey.com> (last visited [13 May 2014])

826 Vinita Nahar, Xue Li and Chaoyi Pang

Part A: Relating to demographic factors;

Part B: Relating to direct cyberbullying;

Part C: Relating to indirect cyberbullying;

Part D: Relating to misinterpreted form of cyberbullying;

Part E: General questions about cyberbullying.

The pilot survey was conducted by interviewing a few UQ students and academics.

After this, modifications were made based on the feedback and the revised questionnaire was posted on the SurveyMonkey website. A filter question 'Have you experienced or been involved in cyberbullying?' was employed to filter out participants who have never been involved in or experienced any form of cyberbullying. In order to determine the best indicators of direct, indirect and misinterpreted form of cyberbullying, an explicit definition of each type of cyberbullying was provided. Also, indicators were independently prepared for each type of cyberbullying. Respondents were asked to answer each item about what constitutes cyberbullying, and the frequency by which they have experienced or been involved in these three types of cyberbullying. The statistical analysis of data is done by computing the Cronbach's alpha, the Spearman's Correlation Coefficient, Linear Regression Analysis and the Coefficient of determination using SPSS. Significance is calculated at 5% and 1% levels.

2.2.1. General Questions about Cyberbullying

This chapter focuses on the Part E of the questionnaire (for the details of Part A, B, C, and D of the questionnaire, please refer [12, 13]. In Part E, three multiple-choice questions were developed regarding the general questions about cyberbullying, such as main sources of cyberbullying, motives of cyberbullying, and participants' reactions to cyberbullying messages. A question to measure the level of severity of cyberbullying based on the percentage of cyberbullying was developed. Four severity levels were defined including 'Severe', 'Moderate', 'Normal', and 'Non-bullying'. Participants were also asked to provide five unusual bullying words they have encountered for the first time.

3. Results and Discussions

3.1. Cyberbullying Prevalence -- Medium, Motive and Reaction

Through the multiple-choice questions, participants were asked to indicate the mediums, causes, and their reactions based on their experience while involved in cyberbullying.

3.1.1. Involvement or Experience of Cyberbullying versus Sources of Cyberbullying (Q6 & Q15)

Given the list of communication tools as a medium through which cyberbullying takes place, as shown in Table 1, 'Social networking websites (SNs)', 'Chat rooms (CR)' and 'Instant Messaging (TM)' are identified as the most common sources for the involvement in cyberbullying activities. The most prevalent tool is social networking websites among

a Correlation between involvement or experience of cyberbullying and sources of cyberbullying

76.3% male and 74.2% female participants of those who have been involved in cyberbullying across all age groups. CR was the second most common medium selected by 68% male and 42% female, with the majority from 12-17 years old candidates, while IM was also an equally likely place for 64% male and 40% females, especially among the 12-17 years olds. Vandebosch et al# [14] conducted a study on cyberbullying in Flanders (Belgium)

among primary school children and students in secondary education. On asking respondents directly whether they had been actively or passively involved in bullying via Internet or mobile phone, they found 10% were victims and 20% were perpetrators in this category. In addition, 61.9% of respondents had been victims and 52.5% had been perpetrators of at least one potentially offensive practice via the Internet or a mobile phone, which are generally considered as a 'form of bullying'.

The internal reliability of the seven sources and experiences of or involvement in cyberbullying is calculated using Cronbach's alpha. The overall alpha coefficient is 0.772 (range if one item deleted, from 0.681 to 0.790), suggested acceptable reliability. The experience and involvement in cyberbullying is a dichotomous variable coded 1 if the respondent answered 'Yes', 2 if a respondent answered 'No'. As shown in Table 1, the correlation coefficients between experience of or involvement in cyberbullying and for TM, phonecalls, CR, SNs and IM is highly significant at the 0.01 level (2-tailed), which shows a strong relationship existed, whereas it is significant for images and emails at the 0.05 level (2-tailed). However, linear regression analysis between dependent variables (experience or involvement of cyberbullying) and independent variables (as given in Table 1 from serial number '1' to '7') suggests that the coefficient of determination (R²), between involvement or experience of cyberbullying and SNs, IM and CR is 49.5%, 46.1% and 41.5% respectively.

This means these independent variables accounted for 49.5%, 46.1% and 41.5% of the total

variation in the dependent variable i.e. involvement or experience of cyberbullying. These

three independent variables are the main sources of cyberbullying, whereas the R 2 between

involvement or experience of cyberbullying and all the seven indicators of Q15 is 63.7%,

as given in Table 2.

3.1.2. Involvement or Experience of Cyberbullying versus Motives of Cyberbullying

(Q6 & Q16)

Participants were then asked for their opinion for the most significant motive for cyberbul-

lying in which they were involved, as given in Table 3. 'To make fun of someone', 'To show

hate', 'To copycat others in bullying activities' and 'To show superiority' were the various

motives given for bullying others. The most common cause of cyberbullying among males

(73.8%) and females (74.2%) between 12 to 30 years of age was 'to make fun of someone'.

'To show hate' was the second most prevalent cause selected by 60.7% of males and 39.8%

of females between 12 to 30 years of age. Of the total, 33.0% of participants mentioned

that 'copycat others in bullying activities' was also a common cause, with the majority of

respondents (66.7%) belonging to the 22-25 years of age group. Double the number of fe-

males than males in the age group 26-25 years and over 30 years said 'To show superiority'

as the fourth most common cause of bullying others online.

c Correlation between involvement or experience of cyberbullying and sources of cyberbullying
cyberbullying from serial number '1' to '6' in Table 3 is highly significant at the 0.01 level (2-tailed), which shows a strong relationship existed. However, linear regression analysis between the dependent variables (involvement or experience of cyberbullying) and independent variables (as given in Table 5.14 from serial number '1' to '6') suggests that the coefficient of determination (R 2), between involvement or experience of cyberbullying and 'to show hate', 'to make fun of someone' and 'to copycat others in bullying activities', is 42.4%, 39.1% and 25.3% respectively. This means these independent variables accounted for 42.4%, 39.1% and 25.3% of the total variation in the dependent variable i.e. experience of or involvement in cyberbullying. These three independent variables are the main motives of cyberbullying, whereas the R 2 between involvement or experience of cyberbullying and all the six indicators of Q16 is 54.0%, as given in Table 4.
3.1.3. Involvement or Experience of Cyberbullying versus Reaction to Cyberbullying (Q6 & Q17)
Respondents were also asked how they have reacted while being involved in cyberbullying. As shown in Table 5 'never replied', 'blocked someone' and 'replied in a bullying manner' were the most common reactions among the participants. The majority of male participants (61%), who also belonged to the age range 12 to 25 years, indicated that they also replied in a bullying manner, while the majority of females (56.0%), generally of all ages, said that they never replied at all. Here we found two interesting things about the reaction to cyberbullying, in that only 12.7% of respondents 'Discussed it with parents/close friend/someone' and 3.2% 'Reported it to the service provider or to the police'. This shows

Cyberbullying Prevalence - Medium, Motive and Reaction 831

that there is an urgent need to spread awareness about cyberbullying so that victims can easily and openly discuss this crucial issue with their parents or service provider, and take action against these activities.

The internal reliability of seven reactions to cyberbullying and experience of cyberbullying is calculated by using Cronbach's alpha. The overall alpha coefficient is 0.688 (range if one item deleted, from 0.564 to 0.717). The experience and involvement in cyberbullying is a dichotomous variable coded 1 if the respondent answered 'Yes', 2 if a respondent answered 'No'. As shown in Table 5, the correlation coefficient between involvement or experience of cyberbullying and all the reactions except 'didn't take it seriously and reply in normal way' and 'reported it to the service provider or to police', is highly significant at the 0.01 level (2-tailed), which shows a strong relationship existed. However, linear regression analysis between the dependent variable (involvement or experience of cyberbullying) and independent variables (as given in Table 5 from serial number '1' to '7') suggests that the coefficient of determination (R^2), between involvement or experience of cyberbullying and 'replied in a bullying manner', 'never replied' and 'blocked someone' is 46.4%, 28.9% and 20.6% respectively. This means these independent variables accounted for 46.4%, 28.9% and 20.6% of the total variation in the dependent variable i.e. involvement or experience of cyberbullying. These three independent variables are the main reactions to cyberbullying, whereas the R^2 between involvement or experience of cyberbullying and all the seven indicators of Q17 is 57.7%, as given in Table 6.

3.2. General Questions about Cyberbullying

Four severity levels of cyberbullying were defined including 'Severe', 'Moderate', 'Normal', and 'Non-bullying'. Respondents were asked to select one suitable range based on the severity level of cyberbullying. The value in percentage terms shows the malevolence of a message. Out of the total, 59.1% respondents selected Severe (86%-100%), Moderate (51%-85%), Normal (16%-50%), and Non-bullying (1%-15%) category of cyberbullying. Participants were also asked to provide five unusual bullying words they had encountered for the first time. We were surprised to see that people were being targeted in the name of caste, religion, race, region, gender, and age etc. We have included these words in our swear-keyword list during the feature space modelling for the cyberbullying detection approaches.

Conclusion

'Social networking websites', 'instant messaging' and 'chat rooms' are the main sources of cyberbullying. Items 'to show hate', 'to make fun of someone', and 'to copycat others in cyberbullying activities' are the main motives of cyberbullying. The main reactions to cyberbullying are 'replied in a bullying manner', 'never replied' and 'blocked someone'. To differentiate real bullying from cyberbullying-like or non-bullying messages, the frequency between sender and receiver over a long period of a time can be seen to demonstrate whether it is an unusual (intentional) act of teasing or a usual (unintentional) act that generally exists between good friends or those in close relationships. However, it is important to note that a too frequent pattern should not be confused with frequent coarse language at a particular time. The unusual patterns over a long period of time should be considered as a clear indicator of real cyberbullying.

Chapter 50

MODULATING VARIABLES OF VIOLENT BEHAVIOR OF AGGRESSIVE-VICTIMS OF BULLYING

Isabel Cuadrado-Gordillo* and Inmaculada Fernández-Antelo

University of Extremadura, Spain

ABSTRACT

Previous research has revealed the existence of a transfer from bullying to cyberbullying of the roles of aggressor and victim. However, the interaction of physical and cyber environments in adolescents not only fosters this transfer or co-occurrence but also accentuates the adoption of more complex roles such as that of aggressive-victim. This profile, simply defined in traditional bullying situations, takes on new dimensions with the many combinations that arise from the co-existence of the phenomena of bullying and cyberbullying.

The aim of the present chapter is to contribute to knowledge of the aggressive-victim profile in the different categories resulting from physical and cyberspace bullying situations. To this end, we considered two questions to answer. The first was to ask what is the actual prevalence of the aggressive-victim in the various forms that this role might be found in the context of bullying and cyberbullying, and then to analyse the behaviours that it involves. The second concerns the variability of these manifestations according to the mode and frequency of the abuses suffered in the two contexts: physical and cyberspace. To answer these questions by presenting the results of research with 1648 Spanish adolescents (aged from 12 to 16 years).

The most relevant contributions of the chapter reside in the identification of variables that modulate the type of abuse that the different categories of aggressive-victims commit against their peers. Gender, mode and frequency of the abuses suffered by aggressive victims are the three variables that influence in the type of violent behavior that they manifest. Also, the results show the victims of aggression in physical or virtual environments tend to use the same context to in turn abuse their peers.

INTRODUCTION

The continuous advances in ICTs, the availability and accessibility of much of the population, especially adolescents, to these resources, as well as the rapid development of a networked society parallel to the presential one, mean that one can expect there to arise quite novel scenarios of action that will impose their own specific rhythms and norms of interaction. To the mechanisms used in physical contexts, one must add those used to relate specifically with others in networked (virtual or cyber) environments. This co-existence of physical and cyberspace scenarios has generated new questions about the processes of victimization and aggression that adolescents experience in them, and about the co-occurrence of the two phenomena (Bonano & Hymel, 2013). Traditional forms of bullying now coexist with modes of aggression that use the resources of the Internet, and that come under the term of “cyberbullying”. There is particularly great interest and uncertainty in determining the scope and implications of the co-existence of the two phenomena – bullying and cyberbullying – amongst youngsters.

BULLYING AND CYBERBULLYING: DEPENDENT OR INDEPENDENT CONSTRUCTS?

The scientific community seems to have reached a consensus on the conceptualization of bullying, understanding it to be an aggressive behaviour that is repeated over time and that is manifest in a physically, psychologically, or socially stronger person who intends to hurt another who is considered weaker (Olweus, 1993). From this definition, three identification criteria are extracted that distinguish the aggressive behaviours specific to bullying situations: the intention to cause physical, psychological, or social harm to another person; repetition of the aggressive behaviour; and an imbalance of power in favour of the aggressor. However, recently, with the emergence of new forms of aggression, the analysis of special and exceptional situations, the consideration of new characteristics and contextual and personal situations, among other factors, imperative compliance with these three criteria is being called into question.

Guerin and Hennessey (2002), for instance, do not believe that intentionality can be considered a defining characteristic of bullying, but rather that an aggressive situation that causes harm can be categorized as bullying, regardless of whether or not there is an intent to harm the victim. Moreover, one can ask in what way the intent of the perpetrator is to be determined.

Similar questions arise about the repetition criterion. Olweus (1993) argues that a single aggressive behaviour could be considered a manifestation of bullying in certain circumstances. However, even today, 20 year later, there has been no specification as to what those circumstances might be. For other authors, an isolated aggression can be catalogued as bullying if the negative effects it has on the victim go on for a long time (Arora, 1996).

Finally, reflections on the criterion of a power imbalance have focused on who should confirm the existence of the abuse of power -- whether the aggressor or the victim -- and on whether such an imbalance must really exist or it is enough for it to be perceived. In this latter aspect, while it has been argued that, indeed, the imbalance of power does not have to be real

but that it is enough that the victim perceives it as such for it to be considered an episode of bullying (Tattum, 1997). Smith, del Barrio, and Tokunaga (2013) note the difficulty faced by researchers to correctly assess the perception that victims construct around the abuse of power. There are also questions about how to quantify any imbalance of power -- whether it should be in the form of a dichotomous scheme expressed in absolute terms (yes or no) or in relative terms covering a greater range (Cook, Williams, Guerra, Kim, & Sadek, 2010).

The discrepancies found concerning the conceptualization of bullying are multiplied even further when it comes to delimiting and defining the phenomenon of cyberbullying. Indeed, this is a concept that is still under construction and that is arousing increasing interest and is the subject of continuous debate among researchers (Law, Shapka, Domene, & Gagné, 2012). While some authors consider cyberbullying to be an indirect form of bullying which needs technological resources for its execution (Slonje & Smith, 2008; Werner, Bumpus, & Rock, 2010), others argue that bullying and cyberbullying are two quite different concepts that have their own characteristics that define and differentiate them (Casas, Del Rey, & Ortega, 2013). The characteristics or criteria attributed to cyberbullying, and which enable it to be differentiated from other aggressive acts carried out between peers with the use of technological and cyber resources include: intent to harm (Kowalski, Limber, & Agatston, 2008), repetition (Slonje, Smith, & Frisé, 2013), imbalance of power (Vandebosch & Van Cleemput, 2008), anonymity (Mishna, Saini, & Solomon, 2009), and publicity (Patchin & Hinduja, 2010). The application of these criteria would allow cyberbullying to be defined as acts of abuse, intimidation, and unjustified aggression that one or more persons carry out against one or more others with the use of technological and cyber resources to enhance the diffusion of the aggression, the repeated re-living of the harm that was done, and the feeling of helplessness.

However, compliance of the concept with these criteria is also the subject of major controversies. Regarding the criterion of the intention to harm, its detection in the cyber context involves difficulties related to the absence of face-to-face communication, the ignorance in many cases of the identity of the aggressor, and the aggressor's ignorance of the consequences their actions cause to others (Menesini & Nocentini, 2009). In the case of the repetition of aggressive behaviour, Slonje et al. (2013) note that repetition does not necessarily imply a succession of violent acts from the same aggressor. They understand that a single abuse can be experienced by the victim on numerous occasions due to the permanent and public nature of virtual communications.

The imbalance of power criterion applied to the cyberbullying phenomenon takes on new dimensions that are not related to the physical, emotional, or psychological superiority of the aggressor, but to an asymmetry in the mastery of ICT skills (Slonje et al., 2013). Moreover, although the anonymity or ignorance of the identity of the aggressor is considered a specific criterion of cyberbullying (Nocentini et al., 2010), there are studies which show that most of the victims recognize their cyber aggressors, and identify them with peers belonging to their own school, their own neighbourhood, or their own immediate environment (Slonje et al., 2013). Finally, the publicity criterion, understood as the open and uncontrolled dissemination of aggressive behaviour, despite having a more widely extended presence in acts of cyberbullying (Patchin & Hinduja, 2010), should not necessarily be considered an essential characteristic defining and delimiting an act of cyberbullying, although its relevance in reflecting the seriousness of the aggression has to be recognized (Nocentini et al., 2010).

Modes of Bullying and Cyberbullying

The differences that exist in how cyberbullying is conceptualized are equally present in determining the forms in which it manifests itself. This is different from the case of studies of traditional bullying, in which there seems to be a consensus on the classification of its forms (Olweus, 1993), with five major categories (social exclusion, physical abuse, threats, sexual harassment, and verbal aggressions), which are in turn subdivided into direct and indirect manifestations. In studies addressing the phenomenon of cyberbullying, one finds significant variations in the categories described, with three types of classification being applied: the technological resources used in the aggression; the action instigating the aggression; and the direct or indirect nature of the abuse.

Regarding the technological resources used to cyberbully others, the advances in ICTs have contributed to a progressive diversification that requires continual updating. Some researchers bin the various resources used into two major categories: the Internet, and mobile telephony (Brighi, Guarini, & Genta, 2009). The former include such actions as sending and receiving e-mails, on-line chats, sharing audiovisual material, being part of a virtual community, etc. But the arrival and rapid spread of smartphones combines these two types of action into one resource, so that the above classification requires some kind of redrafting to match current reality. Other studies establish a more specific classification, considering from seven (Smith et al., 2008) to nine (Patchin & Hinduja, 2010) types of media, including phone calls, text messages, sending photos and videos, e-mails, on-line chat, instant messaging, and websites such as those of social networks. Subsequently, network games have also been included in the list (Tippett & Kwak, 2012). Kowalski et al. (2012) follow this classification but add some subdivisions of the website block. They do not, however, consider that these constitute modes of cyberbullying, but rather simple communication channels that facilitate the perpetration of bullying.

When the classification criterion applied is the action instigating the abuse, Willard (2007) formulated seven modalities of cyberbullying that were subsequently expanded to eight (Kowalski et al., 2008): electronic insults, harassment, denigration, supplanted identity, blackmailing and deceitful cajoling, exclusion, and happy slapping (physical aggression of a person which is recorded on the mobile phone and the posted on the Web). Taking the essence of this classification criterion as referent, Nocentini et al. (2010) put forward four categories of cyberbullying behaviour: verbal (spoken or written), visual, supplanted identity, and exclusion. They admit, however, that this classification can not be considered universal, and would vary depending on the country to which it is to be applied. While in Spain these four categories are accepted as forms of cyberbullying, in Italy only two of them are recognized (verbal and visual), and in Germany supplanted identity is excluded as being considered a criminal act (Menesini et al., 2012).

The diversity of categories is reduced to a dichotomy when the classification criterion is related to the private or public nature of the bullying. The resulting modes are grouped under the terms of direct or indirect, respectively. The direct cyberbullying mode refers to cyberattacks perpetrated against the victim without any public disclosure of them. Only the victim receives the messages, telephone calls, audiovisual material, etc. In contrast, indirect cyberbullying involves either the use of others to harass the victim in cyberspace, or disseminating materials, comments, or messages over the network making the attack public to

an unknown number of people. In the case of using accomplices, it may be that they are not even aware that they are being used or manipulated to inflict pain on others.

TRANSFER OF ROLES BETWEEN PHYSICAL AND CYBER SCENARIOS: NEW TYPES OF AGGRESSIVE-VICTIMS

The co-existence of physical and virtual contexts in today's society of readily available information and knowledge has led to many studies being conducted on adolescents' ability to adapt to these new situations, integrating the two types of scenario and interacting with them practically simultaneously (Laghi, 2013; Mishna et al., 2009; Valkenburg, 2011). In this line, Subrahmanyam, Smahel, and Greenfield (2006) detected a high level of agreement between the behaviour that adolescents manifest in their off-line and on-line lives, with the behaviours presented in cyber environments showing a continuity with or being a mirror of those in physical environments. They therefore understand cyberbullying to be an extension of bullying. Studies examining the co-occurrence of bullying and cyberbullying confirm this relationship between the behaviours that adolescents' manifest in the two types of scenario, and note the transfer of roles from the physical to the virtual context (Kowalski et al., 2012; Pearce, Cross, Monks, Waters, & Falconer, 2011). This implies that adolescents who have been victims or aggressors of bullying will also be so in the cyber environment. Specifically, Juvonen and Gross (2008) find an interval of between 60% and 80% for the coincidence of roles in situations of bullying and cyberbullying in adolescents, and Olweus (2012) finds this figure to reach more than 90%.

In recent years, some studies have shown that many of the cyberbullies previously played the role of aggressor in traditional bullying. Ybarra and Mitchell (2004) found 3% of the victims of bullying to also be victims of cyberbullying. Smith et al. (2008) report a much greater prevalence, with 14.1% having the victim's role in both physical and cyber contexts. Juvonen and Gross (2008) found 85% had experienced at least one episode of bullying and one episode of cyberbullying in the previous 12 months. However, their study reveals neither whether the roles of victim and cybervictim overlapped nor which came first.

Subsequent studies also present conflicting data. For example, Hemphill et al. (2012) found that few youngsters (7.3%) are involved simultaneously in situations of traditional and cyber bullying. This is in line with the finding of Gradinger, Strohmeier and Spiel (2009) that there was co-occurrence of these two roles in 6.2% of adolescents. In contrast, Olweus (2012) reports that very few youngsters have a purely cybervictim or cyberaggressor role. Instead there is a very strong overlap of roles between the physical and the virtual contexts. In particular, 88% who had felt themselves victims of at least one situation of bullying in the past two months had also suffered episodes of cyberbullying. This co-occurrence of roles has served as a guide for some cyberbullying prevention measures by considering the role played previously in bullying situations as a predictive factor.

The relationship between these two phenomena has also been studied in the reverse sense, with some authors noting a low likelihood of first experiencing episodes of cyberbullying and subsequently being involved in bullying situations (Del Rey, Elipe, & Ortega-Ruiz, 2012; Hemphill et al., 2012).

The study of the co-existence of bullying and cyberbullying has not been limited to the analysis of the coincidence of the dual roles, such as would be the case with a traditional bully becoming a cyberbully, or with the victim of traditional bullying becoming the victim of cyberbullying. There is less empirical evidence about the other more complex situations which can arise and which pose new questions. The study of the co-occurrence of bullying and cyberbullying has yielded new data which require variations in the definition of other roles such as that of the aggressive-victim. For instance, Sabella, Patchin, and Hinduja (2013) argue that the victims of bullying can take on a different role in cyberspace and become cyberbullies. Those authors understand that since these children can not retaliate presentially in the classroom, they use technological means by way of compensation. Del Rey et al. (2012) reinforce this association of roles in showing that victimization in physical contexts can help to predict cyber abuse. However, Hemphill et al. (2012) suggest that the role of cyberaggressive-victims can only be understood as something temporary and that cyberaggressive behaviour can not be predicted from the experiences of victimization in traditional bullying. These authors argue rather for the establishment of a new category of cyber aggressive-victim and note that the victims in cyberbullying episodes show, at least in part, a tendency to manifest cyberaggressive behaviour.

This co-existence of roles has also been studied by Li (2007), but in a different direction. That author analyses the likelihood that those playing the different roles in traditional bullying situations can become cybervictims. Among her conclusions is that there is a high probability that both victims and aggressors of bullying will become cybervictims.

In connection with the transfer of the role of the aggressive-victim of bullying to cyber scenarios, Smith et al. (2008) note that there the observations have not been of any stability of roles between the two contexts, but rather of a shift towards the figure of the cyberbully. These discrepancies in the various investigations reported in the literature, and the unexplored relationships concerning the co-existence of the phenomena of bullying and cyberbullying in other roles such as the aggressive-victim, point to the need for new studies aimed at achieving a more comprehensive view of the reality of teenagers' lives that will contribute to enhancing the effectiveness of prevention and intervention measures.

GENDER DIFFERENCES

The adoption of one or another role as a function of gender, and the influence of this variable on the manifestation of different types of aggressive behaviour, have been extensively studied in bullying situations (Smith, Cowie, Olafson, & Liefoghe, 2002). For the case of aggressive-victims of bullying, Cuadrado and Fernández (2009) confirm a trend towards the predominance of the prevalence of boys over girls, although they state that when the frequency of the aggression is 'sometimes', the trend inverts, and more girl aggressive-victims are detected than boys. The opposite is the case when the frequency increases to 'always'. Moreover, those authors note that the modality of bullying suffered changes the ratio between boys and girls who play that role, with there being detected more girls when the aggression is related to indirect verbal abuse (spreading false rumours) and more boys when there is direct physical aggression, threats, verbal abuse, or social isolation.

However, the results of studies on the influence of the gender variable on the roles involved in cyberbullying have often been contradictory. While some studies conclude that there are no significant gender differences in the roles taken (aggressor or victim) in cyberbullying among adolescents (Livingstone, Haddon, Görzig, & Ólafsson, 2011), others do find such gender differences, although they recognize that these differences are complex (Tokunaga, 2010). In this regard, it is noted that girls are more likely to participate as cybervictims and boys as cyberbullies (Salmivalli & Poyhonen, 2012). Li (2006), while finding no gender differences in the prevalence of cybervictims, states that the number of cyberbullies is twice as high in boys than in girls. In contrast, Rivers and Noret (2010) find that, regardless of the role played, girls are more involved than boys in cyberbullying situations. Other work has nuanced these differences by indicating that the greater participation of girls is generally associated with indirect relational cyber-harassment through text messages or phone calls (Smith, 2012). While Monks, Robinson, & Worlidge (2012) find no significant association between gender and cybervictims, they find such an association between gender and cyberbullies, with the prevalence of girls being higher than that of boys in the use of a wide range of modes of cyberbullying.

The disparity and contradictions in the results, as well as the lack of studies which address the differences of gender in roles such as that of aggressive-victim in its various manifestations that originate from the co-occurrence of the phenomena of bullying and cyberbullying, highlight the need to undertake further research to clarify the situation and provide a solid basis for the design of new prevention and intervention programs addressing violence among adolescents.

ANALYSIS OF VIOLENT BEHAVIOR OF AGGRESSIVE-VICTIMS. AN EMPIRICAL STUDY

Previous research has revealed the existence of a transfer from bullying to cyberbullying of the roles of aggressor and victim. However, the interaction of physical and cyber environments in adolescents not only fosters this transfer or co-occurrence but also accentuates the adoption of more complex roles such as that of aggressive-victim. This profile, simply defined in traditional bullying situations, takes on new dimensions with the many combinations that arise from the co-existence of the phenomena of bullying and cyberbullying. The few studies that have been published on this issue have not been able to provide conclusive data allowing one to gain a clear vision of these new and varied forms of bullying that teenagers face, and thereby better match bullying prevention and intervention measures to today's reality.

In the present chapter, we try to contribute to knowledge of the aggressive-victim profile in the different categories resulting from physical and cyberspace bullying situations. To this end, we considered two questions to answer. The first was to ask what is the actual prevalence of the aggressive-victim in the various forms that this role might be found in the context of bullying and cyberbullying, and then to analyse the behaviours that it involves. The second concerns the variability of these manifestations according to the gender, mode and frequency of the abuses suffered in the two contexts: physical and cyberspace. To answer these questions by presenting the results of research carried out in Extremadura (Spain), involving 1648 adolescents (48.9 % girls; $SD = .5$) with ages between 12 and 16 years ($M = 14.1$, $SD = 1.3$).

The instrument used for data acquisition was a revised version of the questionnaire applied by Cuadrado and Fernández (2009) to identify and define the profile of the aggressive-victim of bullying. The modifications made to this questionnaire consisted of the insertion of two new categories that corresponded to the phenomenon of cyberbullying: cybervictimization and cyberbullying itself. Thus, the final version of the questionnaire consisted of four categories: victimization, bullying, cybervictimization, and cyberbullying. The first two (corresponding to traditional bullying) comprise behaviour related to six modes of aggression: exclusion, verbal aggression, direct physical aggression, indirect physical aggression, threats, and sexual harassment. The last two (corresponding to cyberbullying) comprise behaviour related to four modes of cyberaggression (Nocentini et al., 2010): written-verbal aggression, visual aggression, impersonation, and exclusion. The response options to all the items were presented on a 4-point Likert scale indicating the frequency of the attack suffered or perpetrated in the preceding two months: 1 – never; 2 – once or twice; 3 – once a week; and 4 – various times a week.

Continuity vs. Discontinuity between Physical and Cyber Contexts as a Key Element in the Identification and Classification of Aggressive-Victims

Depending on the type of bullying suffered and the means used for its perpetration, the role of victim acquires a twofold dimension: victim (when the abuse corresponds to traditional modes of bullying and is manifested in presential, classroom contexts), and cybervictims (when the abuse is experienced through the Internet, or by electronic or telephony devices). Similarly, the role of aggressor also has this twofold dimensionality: bullies (in traditional bullying) and cyberbullies (when ICTs are used to perpetrate the abuse). The combination of these dimensions yields four profiles of adolescents who are themselves bullied and then turn to bullying others of their peers: aggressive-victims (166 boys, 123 girls), cyberaggressive-victims (93 boys, 59 girls), aggressive-cybervictims (37 boys, 30 girls), and cyberaggressive-cybervictims (30 boys, 23 girls).

The values of Pearson's correlation coefficient and the level of significance found for these four types of aggressive-victim indicate that their presence in the school context is neither random nor extraordinary: aggressive-victims (.485**), cyberaggressive-victims (.502**), aggressive-cybervictims (.280*), and cyberaggressive-cybervictims (.637**).

The composition of these four modes corresponds to pure profiles. However, the results revealed the existence of a group of 89 participants who did not strictly fall in to any single one of these categories. These were aggressive-victims who were being bullied in both the physical and the virtual contexts, and who in turn, rather than adopting a specific pattern of perpetrating aggression, combined different modes of bullying and cyberbullying to hurt their victims. In the present study, we have excluded this group of adolescents from the analysis since they present behavioural patterns shared with members of the four "pure" aggressive-victim types.

Modulating Variables of Violent Behavior of Aggressive Victims

The results reveal the existence of three variables that modulate the type of abuse that the different categories of aggressive-victims commit against their peers: the type of aggression

suffered, gender of the victim and the frequency of the abuse suffered. Then we analyses the profile of different categories of aggressive-victims depending of each of these modular variables.

Abuse Suffered as a Determinant of the Type of Aggression Committed

The analysis of the synergy established between the modes of bullying suffered and perpetrated shows significant differences depending on the category of aggressive-victims.

Aggressive-Victims of Traditional Bullying

The results show that, regardless of the type of abuse suffered, the type of aggression they usually perpetrate against their peers is that of a verbal character (insults, name-calling, and spreading false rumours), followed by indirect physical (hiding, breaking, or stealing personal items). They also show that sexual harassment is just a residual behaviour among the totality of manifestations of violence. Even in those cases, however, there was no significant relationship between the types of bullying suffered and perpetrated (Table 1).

Table 1. Correlations between abuses suffered and perpetrated by aggressive-victims

Bullying perpetrated Bullying suffered	Exclusion	Verbal	Indirect physical	Direct physical	Threats	Sexual harassment
Exclusion	.207	.502**	.538**	.291	.163	.027
Verbal	.157	.421*	.476*	.202	-.108	.098
Indirect physical	.235	.605**	.647**	.606**	.664**	.049
Direct physical	.347*	.754**	.275	.868**	.623**	.103
Threats	.170	.597**	.546**	.363*	.121	-.058
Sexual harassment	.239	.591**	.360*	.149	.695**	.156

* $p < .05$, ** $p < .01$.

However, there are a certain mimicry of the type of bullying perpetrated with the type of bullying experienced, whether verbal (.421*), indirect physical (.647**), or direct physical (.868**). Also, those who have been victims of direct physical bullying tend to attack their peers with indirect physical bullying (.606**), or threats (.363*). And those who had suffered indirect physical bullying tended to exclude others (.538**) and to attack with insults (.476*), indirect physical bullying (.647**), threats (.546**) y sexual harassment (.360*).

Cyberaggressive-Victims

The cyber abuse that the cyberaggressive-victims mostly commit are verbal (spoken or written) and visual, independently of the aggression suffered (Table 2). The results also show that supplanted identity is a behaviour that is often used by those who suffer intimidating threats from their peers (.367*). Similarly, exclusion from forums and virtual spaces tends to be behaviour adopted by those who have suffered isolation in physical contexts (.618**). Also, they show an inclination to disseminate compromising or ridiculing audiovisual material of other classmates and to send messages via telephone or the Internet (.543**), or to make threatening telephone calls in order to instil fear and cause pain (.369*).

Table 2. Correlations between abuses suffered and perpetrated by cyberaggressive-victims

Cyberbullying perpetrated Bullying suffered	Written-Verbal	Visual	Impersonation	Exclusion
Exclusion	.369*	.543**	.333	.618**
Verbal	.257	.259	-.101	.176
Indirect physical	.565**	.490*	-.111	.385*
Direct physical	.283	.579**	.117	-.078
Threats	.580**	.588**	.367*	.254
Sexual harassment	.462*	.756**	.673**	.302

* $p < .05$; ** $p < .01$.

The cyberaggressive-victims who suffer indirect physical bullying tend to commit cyber-attacks via telephone calls, on-line chats, or text messages (.565**). Those who suffer threats and sexual harassment also show a very similar pattern of aggressive behaviour, with cyberbullying transmitted visually or verbally, or supplanting the identity of others to commit misdemeanours or to ridicule the victim in front of the rest of their companions (Table 2).

Aggressive-Cybervictims

The analysis of the bullying behaviour perpetrated by aggressive-cybervictims shows only three adolescents who turn to sexual abuse to hurt their peers, and that this manifestation was unrelated to any particular mode of cyberaggression suffered. Also, regardless of the type of bullying suffered, the adolescents in this group attack their peers with insults, name-calling, or spreading rumours (verbal), hiding, breaking, or stealing their personal items (indirect physical abuse), and hitting, kicking, and shoving (direct physical abuse) (Table 3).

Table 3. Correlations between abuses suffered and perpetrated by aggressive-cybervictims

Bullying perpetrated Cyberbullying suffered	Exclusion	Verbal	Indirect physical	Direct physical	Threats	Sexual harassment
Written-Verbal	.332	.706**	.693**	.635**	.324	.112
Visual	.847**	.799**	.429*	.896**	.771**	.056
Impersonation	.235	.605**	.647**	.606**	.664**	-.091
Exclusion	.301	.671**	.466*	.584**	.417*	-.217

* $p < .05$; ** $p < .01$.

Those who had suffered abuse consisting of the dissemination of compromising visual or audiovisual material added to their register of aggression in response the modes of social exclusion (.847**) and threats (.771**). This latter mode was also reported by those victims who had had their on-line identity supplanted (.664**) and by those who had been excluded from social networks, forums, on-line chat rooms, or other types of virtual events (.417*).

Cyberaggressive-Cybervictims

With respect to the cyberaggressive-cybervictim group, there was a certain mimicry between the types of bullying suffered and perpetrated except in the case of those who had suffered supplanted identity who responded with other modes of aggression such as sending messages or making anonymous calls (.805**), exclusion (.587*), or dissemination of visual material that threatens the integrity of their victim (.421*). Regardless of the mode of bullying suffered, this group of teenagers used many modes of bullying to attack their peers. This was especially so of those who had been the object of intimidating or harassing messages or telephone calls (Table 4).

Table 4. Correlations between abuses suffered and perpetrated by cyberaggressive-cybervictims

Cyberbullying perpetrated Cyberbullying suffered	Written-Verbal	Visual	Impersonation	Exclusion
Written-Verbal	.702**	.760**	.829**	.675**
Visual	.361	.711**	.445*	.324
Impersonation	.805**	.421*	-.247	.587*
Exclusion	.403*	.279	.126	.789**

* $p < .05$; ** $p < .01$.

Variability of Violent Responses of Aggressive-Victims by Gender

The results indicate that boys and girls have different patterns of behavior and react differently to abuse sufferers. Then, we describe the profile that defines of the different categories of aggressive victims based on their gender.

Aggressive-Victims of Traditional Bullying

The differences between boys and girls in the aggressive behaviours that they manifest depend on the abuse they have suffered. Boys who have been verbally and physically abused show a mimetic behaviour when they attack their peers (Table 5). In girls, however, this mimicry is only found in the case of direct physical abuse (.904**).

Table 5. Correlations between abuses suffered and perpetrated by aggressive-victim by gender

Bullying perpetrated Bullying suffered	Exclusion		Verbal		Indirect physical		Direct physical		Threats		Sexual harassment	
	Boys	Girls	Boys	Girls	Boys	Girls	Boys	Girls	Boys	Girls	Boys	Girls
Exclusion	.288	-.162	.587**	.570**	.329	.815**	.244	.529*	.146	.116	.071	.019
Verbal	-.130	.578**	.495**	-.321	.490*	.446*	.257	-.164	.381	-.212	.103	-.071
Indirect physical	.311	-.160	.490*	.741**	.583**	.497*	.475*	.720**	.454*	.903**	.055	.
Direct physical	.539**	-.468	.674**	.755**	.379*	-.184	.819**	.904**	.411*	.883**	.097	.113
Threats	.285	-.381	.691**	.645**	.593**	.362	.300	.220	.232	-.712**	-.064	.009

Table 5. (Continued)

Bullying perpetrated Bullying suffered	Exclusion		Verbal		Indirect physical		Direct physical		Threats		Sexual harassment	
Sexual harassment	.157	.111	.436*	.671*	.257	.265	-.217	-.184	.638*	.840**	.184	.145

* $p < .05$; ** $p < .01$.

Other gender differences indicate that boys who have been victims of direct physical aggressions diversify their own violent behaviour, resorting to exclusion (.539**), threats (.411**), verbal (.674**), and physical (direct and indirect, .819** and .379*) aggression. In contrast, girls tend to abuse their peers through verbal (.755**), direct physical (.904**), and threat (.883**) aggression. When the aggression suffered corresponds to patterns of social exclusion, boys tend to resort to verbal abuse, whereas girls also incorporate into their behaviour direct and indirect physical abuse. Finally, when the adolescents suffer threats, boys abuse their peers verbally (.691**) and with indirect physical aggression (.593**), and girls use verbal abuse (.645**) but not threats (-.712**).

Cyberaggressive-Victims

There is a stronger correlation between the modes of abuse suffered and perpetrated in the case of girls. Boys do not have a well-defined mode of cyberaggressive behaviour, except for the cases in which they are victims of exclusion or threats (Table 6).

Table 6. Correlations between abuses suffered and perpetrated by cyberaggressive-victims by gender

Cyberbullying perpetrated Bullying suffered	Written-Verbal		Visual		Impersonation		Exclusion	
	Boys	Girls	Boys	Girls	Boys	Girls	Boys	Girls
Exclusion	.451*	.508	.616**	.406	.376	.234	.511*	.739**
Verbal	.197	.649**	.193	.545**	.171	.551**	.093	.315
Indirect physical	.371	.711**	.316	.912**	-.250	.217	.261	.488*
Direct physical	.356	.701*	.132	.870**	-.151	.447	-.145	.006
Threats	.645**	.304	.600**	.845**	.441*	.624*	.197	.327
Sexual harassment	.022	.926**	.423	.686*	.412	.603	.334	.420

* $p < .05$; ** $p < .01$.

In the case of the boys, visual aggressions can be predicted from previously experienced aggression in physical contexts, e.g., exclusion (.616**) and threats (.600**). Also, when they receive threats, they tend to manifest verbal (spoken or written) aggressive behaviour (.645**). For the girls there are mimicry of the abuse committed with that suffered in the cases of exclusion (.739**) and verbal abuse (.649**). Experiences of being victims of threats, and

direct and indirect physical abuse were predictors of visual aggressive behaviours (.845**, .870**, .912**, respectively).

Aggressive-Cybervictims

The results also showed significant gender differences in the synergistic relationship between the modes of abuse suffered and perpetrated. Overall, boys present more diversified aggressive behaviours than girls, except in the cases in which they are victims of impersonation (Table 7). In those situations, girls resort to threats (.586*) and indirect (.716*) and direct (.560*) physical aggression, while boys are inclined to abuse others mainly through social isolation (.554*).

Table 7. Correlations between abuses suffered and perpetrated by aggressive-cybervictim by gender

Bullying perpetrated Cyberbullying suffered	Exclusion		Verbal		Indirect physical		Direct physical		Threats		Sexual harassment	
	Boys	Girls	Boys	Girls	Boys	Girls	Boys	Girls	Boys	Girls	Boys	Girls
Written-Verbal	.337	.125	.604*	-.558	.759**	-.778	.831**	.857*	.590*	.765	.112	.
Visual	.635**	.807*	.790**	.463	.546*	-.271	.700**	.807*	.342	.919**	.097	-.103
Impersonation	.554*	-.226	.524	-.513	.308	.716*	.502	.560*	.287	.586*	.016	.238
Exclusion	.270	.578	.794**	.625	.574*	.802*	.629*	.590	.735*	.829*	-.119	-.308

* p<.05; ** p<.01.

A result that stands out refers to the verbal abuse perpetrated by aggressive-cybervictims. In the case of boys, this behaviour manifests itself when they are victims of verbal (.604*), visual (.790**), or exclusion (.794**) cyberaggression, whereas in girls this behaviour is uncorrelated with any of the modes of cyber abuse suffered (Table 7).

Prediction of aggressive behaviour is more limited in the case of the girls than in that of the boys. Threats are the commonest type of abuse used when the girls had been victims of cyber-exclusion (.829*) or visual aggression (.919**). For the boys, when the abuse suffered is verbal, they tend to attack others through both direct (.831**) and indirect (.759**) physical aggression. When the aggression suffered is visual, the boys' aggressive behaviour tends to consist of insults and spreading false rumours (categorized together under the verbal mode: .790**) or direct physical abuse (.546*). When the abuse suffered is cyber-exclusion, the boys' manifest aggression in the form of threats (.829*).

Cyberaggressive-Cybervictims

The analysis of gender differences shows that, when this group of adolescents suffers impersonation, while boys present no well-defined pattern of cyberaggression (Table 8), girls are strongly inclined to commit verbal (.954**), visual (.764**), or exclusion (.818**) modes of cyber abuse. Also, when the aggression suffered is related to cyber-exclusion, as well as the

mimetic behaviour presented by these cyberaggressive-cybervictims, boys also tend to commit verbal abuse (.540*), whereas girls opt for visual abuse (.677*).

Table 8. Correlations between abuses suffered and perpetrated by cyberaggressive-cybervictims by gender

Cyberbullying perpetrated	Written-Verbal		Visual		Impersonation		Exclusion	
Cyberbullying suffered								
	Boys	Girls	Boys	Girls	Boys	Girls	Boys	Girls
Written-Verbal	.615*	.867**	.520*	.917**	.850**	.748*	.749**	.517
Visual	.332	.463	.727*	.713*	.526	-.316	.302	.420
Impersonation	.504	.954**	.135	.764**	.071	-.460	.394	.818**
Exclusion	.540*	.298	.155	.677*	.192	-.214	.720**	.819**

* $p < .05$; ** $p < .01$.

Synergy between Frequency of the Abuse Suffered and the Aggression Perpetrated

In this chapter we present the results of the correspondence between the frequency of the aggressive-victim's being or having been mistreated and the frequency with which they themselves attack their peers in each of the categories of victims aggressive analyzed.

Aggressive-Victims of Traditional Bullying

There are a positive correlation between the frequencies of the abuse suffered and the abuse perpetrated. In this regard, about 60% of the aggressive-victims who had been subjected to social exclusion, threats, or verbal or physical aggression had suffered these episodes of bullying with a frequency of 'once or twice' in the preceding 2 months, and had resorted to attacking their peers with this same frequency. Also, more than 20% of the aggressive-victims who had been subjected to social exclusion, or direct and indirect physical or verbal bullying had suffered these episodes 'various times a week', and had resorted to these or other types of bullying with the same frequency. However, this percentage varied in the case of 'various times a week' aggressive-victims of sexual harassment, being 35.2%. The correlation established between the frequencies of bullying suffered and perpetrated indicates that these sexually harassed aggressive-victims 'various times a week' threaten and attack verbally and indirectly physically others of their peers. Similarly, there were 12% of the aggressive-victims who are threatened 'various times a week' and resorted to verbally and physically abusing others with the same frequency.

Finally, analysis of the 'once a week' frequency of bullying revealed that more than 20% of the aggressive-victims suffering sexual or physical (direct and indirect) abuse or threats resorted to perpetrating bullying with this same frequency. Only 10% of the aggressive-victims who suffered verbal abuse or social exclusion stated that they suffered these abuses 'once a week' and attack others with verbal or indirect physical abuse with the same frequency.

Cyberaggressive-Victims

Regarding the relationship between the frequencies of bullying suffered and perpetrated, over 60% of the cyberaggressive-victims who are subjected to situations of exclusion, threats, and verbal bullying suffered these attacks and attacked others 'once or twice' in the preceding two months. About 50% of the cyberaggressive-victims who suffered direct and indirect physical bullying also experienced these situations 'once or twice' and attacked their peers with the same frequency. Only 38% of the sexually harassed cyberaggressive-victims suffered this mode of bullying 'once or twice', and they tended to respond perpetrating written-verbal, visual, and impersonation attacks with the same frequency.

When the frequency of the bullying increases to 'once a week', the results showed that around 20-29% of the cyberaggressive-victims suffering threats, direct and indirect physical bullying, or sexual harassment with this frequency committed attacks against their peers also 'once a week'. In contrast, only 10% of the cyberaggressive-victims who suffered exclusion reported a frequency of 'once a week' and perpetrated attacks with this same frequency in the modes of verbal or visual bullying and supplanted identity.

Finally, the results showed that over 30% of the cyberaggressive-victims who suffered sexual harassment and direct physical bullying experienced and perpetrated these episodes with a frequency of 'various times a week'. Also, about 22% of the cyberaggressive-victims who suffered exclusion and indirect physical bullying experienced these episodes 'various times a week', and perpetrated attacks in the modes of exclusion, written-verbal, and visual bullying with the same frequency. In the case of cyberaggressive-victims who were subjected to presential threats, 10.6% reported suffering these situations 'various times a week', and tended to supplant the identity of others in cyberspace, disseminate compromising audiovisual material, or send intimidating messages with the same frequency.

Aggressive-Cybervictims

The frequency of the bullying suffered greatly influenced how often this group itself bullied. Of the aggressive-cybervictims who suffered bullying related to the dissemination of upsetting, compromising, or insidious visual material, 69.6% had experienced these attacks 'once or twice' in the preceding two months, 21.7% 'once a week', and 8.7% 'various times a week'. The correlation found between the frequencies of bullying suffered and perpetrated indicates that these aggressive-cybervictims tend to bully in physical contexts with the same frequency as that with which they themselves suffer cyber-attacks.

In the case of the aggressive-cybervictims who had suffered supplanted identity abuse, 45.5% had experienced this mode of bullying and themselves bullied other peers 'once or twice' in the preceding two months, 36.4% 'once a week', and 18.1% 'various times a week'. The results were similar for the frequencies of bullying suffered and perpetrated by aggressive-cybervictims who had been subjected to on-line exclusion.

Of the aggressive-cybervictims who had suffered written-verbal cyberbullying, 22.7% had experienced these episodes 'once or twice' in the preceding two months and had perpetrated verbal and physical bullying with the same frequency. Similarly, 45.5% of these aggressive-cybervictims had experienced these episodes 'once a week', and they reported this same frequency of their own bullying attacks. The remaining 31.8% had experienced these episodes

'various times a week', and themselves subjected their peers to bullying in physical contexts with the same frequency.

Cyberaggressive-Cybervictims

Results show that, of the cyberaggressive-cybervictims who suffered bullying related with the dissemination of written messages or telephone calls, 36.7% stated to have experienced these situations 'once or twice' in the preceding two months, another 36.7% 'once a week', and 26.6% 'various times a week' in the preceding two months. The correlation between the frequencies of suffering and perpetrating abuse showed these cyberaggressive-cybervictims to abuse their peers with the same frequency that they themselves suffered written-verbal cyberbullying.

When the type of bullying suffered corresponded to impersonation or exclusion, the percentage of cyberaggressive-cybervictims suffering and perpetrating attacks 'once or twice' in the preceding two months was close to 45%, 'once a week' was around 35%, and 'various times a week' was around 20%.

In the case of cyberaggressive-cybervictims who were victims of visual material disseminated to violate their dignity, 44% of them had experienced these attacks 'once or twice' in the preceding two months and had bullied others in the same way and with the same frequency. Some 28% of this group had experienced these visual attacks 'once a week', and had attacked others with the same frequency by means of visual and impersonation modes of bullying. The same results were obtained for the 'various times a week' frequency of attack.

DISCUSSION

The co-occurrence of bullying and cyberbullying in today's dual society calls for specific intervention measures designed to forestall the emergence of new problems and to slow the increase and diversification of violent forms of behaviour. The modulating variables provided in this chapter, together with the definition of the profiles of the different categories of aggressive-victims, may contribute to a deeper understanding of the processes of victimization and aggression that adolescents experience in both physical and cyber contexts. Such knowledge is considered to be one of the keys in the search for effective anti-bullying and anti-cyberbullying programs since it will allow specific actions to be designed for the particular characteristics of those involved and their prior experiences of victimization or cybervictimization, instead of relying on the myths that have grown around these phenomena or on certain general notions that might explain them (Sabella et al., 2013).

Modulating variables shown in this chapter are summarized in three: type of abuse suffered, gender of the victim and the frequency of the aggression suffered.

A first variable is the type of abuse suffered. In the four categories of aggressive-victims analysed, a certain mimicry is found between the modes of abuse suffered and perpetrated, especially when the aggression suffered corresponds to indirect or verbal aggression. This mimicry has been described in previous studies (Cuadrado & Fernández, 2009), and some authors explain it on the basis of the perceptions that these adolescents have of the potential

that the type of abuse they have suffered has to cause pain to their peers (Hughes & Trafimow, 2012). The experience of the harm that a certain mode of abuse has caused them can give rise to false beliefs about the potential of that behaviour to hurt others, without their realizing that the others may not have the same vulnerabilities, and will not, therefore, necessarily suffer the same consequences. In the cases in which this mimicry does not occur, there is a synergistic relationship between exclusion suffered, in either physical or cyber contexts, and primarily verbal and indirect physical aggressive behaviour perpetrated. Schwarzwald, Koslowsky, & Brody-Shamir (2006) explain the tendency towards these modes of aggression by referring to the imbalance of power criterion. The situations of victimization which they had suffered previously caused these adolescents to experience such a strong sense of inferiority that it is difficult for them to confront their peers directly.

A second variable is the gender variable. The relevance of this variable lies not only in the detection and identification of aggressive-victims and their subsequent classification into the four resulting categories (aggressive-victim of traditional bullying, cyberaggressive-victim, aggressive-cybervictim, and cyberaggressive-cybervictim), but also in its mediating role in determining the abusive behaviour they demonstrate against their peers. With respect to identification and classification, there is a stronger correlation in the case of girls towards performing the roles of cyberaggressive-victim and cyberaggressive-cybervictim. Girls give greater importance than boys to the imbalance of power criterion in situations of bullying and cyberbullying, which may in part explain that their aggressive behaviour is preferentially committed in a cyber environment as a result of the anonymity that affords them when they are hurting their peers (Cuadrado, 2012). In the same sense, the tendency of boys towards direct aggressive behaviours, more characteristic of physical than cyber scenarios (Erdur-Baker, 2010), could explain the strength of their correlations in the aggressive-victim and aggressive-cybervictim categories.

The last variable is correspondence between the frequency of the aggressive-victim's being or having been mistreated and the frequency with which they themselves attack their peers. In particular, it is found that those who suffer occasional episodes of bullying and cyberbullying, themselves also bully others sporadically. Likewise, those who are constantly being mistreated themselves adopt continual aggressive behaviours.

Chapter 51

BULLYING AMONG TRAINING SCHOOL MALE ADOLESCENTS AND MALE ADULT PRISONERS: DESCRIPTIVE ANALYSIS

Kristi Kõiv, PhD, Associate Professor*
and Liine Maasikas, MA, MA student
Institute of Education, University of Tartu, Estonia

ABSTRACT

The current study aims to address the lack of research exploring differences between male adult prisoners and male juvenile training school students in relation to their bullying behavior.

A training school is a correctional facility that is used for the custody and re-education of juvenile offenders. Training schools are a part of the educational system in Estonia and they are used to prepare incarcerated youth for returning to society. The first sample of this study consists of all 53 male adolescent offenders (13–17 years old with average age 14.7 years) at the only maximum security male juvenile training school in Estonia, and the second sample consists of 105 male adult offenders (21–66 years old with average age 33.1 years) at one of four maximum security male prisons in Estonia.

The present study used a self-reported questionnaire developed by Ireland and Archer (1996) to provide not only a descriptive analysis of the nature and extent of bullying among adolescents in training school and among adults in prison, but also a comparison between two study group to assess the hypothesis that adolescents' bullying would involve a greater proportion of direct forms than adults' would, and that adults' bullying would display a greater proportion of indirect forms than youth' would.

The perceived extent of bullying was higher in prison compared with juvenile training school. Bullying in the juvenile training school was predominately physical (direct) but adult reported a higher frequency of indirect bullying in prison. A particular characteristic of individuals (e.g., vulnerable) was viewed as being predisposed to become a victim of bullying and various reasons (e.g., victims are easy targets) were suggested as to why a person was bullied, but adults in prison were significantly more likely than juveniles in

* Corresponding Author's Email: kristi.koiv@ut.ee.

training school to suggest sex offenders, and adolescents more likely than adults the physical weakness of victim. Bullying was seen to occur at locations out of sight of staff but more in living areas in the prison and more at school and private areas in the juvenile training school. More juveniles at training school than prison inmates reported that both they and staff were willing to help the victims of bullying. A relatively higher percentage of inmates in both institutions - prison and training school, admitted to being bullies, victims and bully/victims with on average 2 to 4 bullying incidents in previous week.

Keywords: Bullying, prison, training school, male adolescent and adult inmates

INTRODUCTION

Research on bullying in diversity of settings (Monks, Smith, Naylor, Barter, Ireland & Coyne, 2009) has grown rapidly during the last two decades, initially in schools but also in other settings and relationships: between siblings, in children's homes, in prisons, and in the workplace among children, adolescents, and adults. Common trends across contexts include age and sex differences. For example, general trends in prison bullying can in part be understood in terms of the developmental model (Björkqvist, Österman, & Kaukiainen, 1992) whereas younger inmates are more likely to use direct and physical forms of bullying and older inmates more indirect and less physical bullying forms; and with special trends in prison settings. Namely, indirect aggression is used to the same extent (or even more), than direct aggression as and due to its covert nature, it reduces the risk of being caught and of the perpetrator being subjected to any official punishment (Ireland, 1999a).

Main settings of studying bullying are schools (overview: Smith, 2011) and prisons (overview: Ireland, 2011), but bullying in training schools is a setting that interweaves these two abovementioned study areas. Bullying in prison occurs more frequently than among schoolchildren (Ireland 2005). For example, between 15 and 20 per cent of children and adolescents experienced intense and repeated victimization during their school years, which give an example to the extensive range of research on school bullying in whole world (Smith and Brian, 2000; included Estonia: Kõiv, 2009). Nearly two decades there is a scientific interest to the topic of prison bullying with leading role of studies in the United Kingdom (Ireland, 2002a).

Within school context, bullying tends to be defined as specific phenomenon as a subsection of aggressive behavior (intended, repeated attack with power imbalance), whereas in the prison context it is seen within the wider approach indicating that frequency, duration and intent as criteria for defining bullying may be not always applied (Coyne & Monks, 2011; Ireland, 2005a). But other researchers (Edgar, 2005) have argued that repetition is an essential element for behavior to be labeled bullying in prison. Ireland (1999a) has noted that one way in which researchers try to avoid definitional problems in bullying research is to present respondents with a definition of the phenomenon. In addition to the different definitions applied to prison-based studies, a variety of methods have also been used to collect data: interviews, official records, and self-report questionnaires (Ireland, Jarvis, Beck, & Osiowy, 1999), and in this field research has commonly used self-reports to measure the nature and the extent of bullying (included direct measurement of bullying, and measurement of behavior indicative of bullying),

which have been found to be more reliable and valid than either staff or peer-reports (Connell and Farrington, 1997).

This chapter compares the nature and extent of bullying by male inmates in two settings – one is juvenile training school and the other is adult male prison. Training schools are correctional facilities that are used for the custody and re-education of juvenile offenders. The primary focus of training schools is to provide care, treatment, education and custody for juveniles committed by the courts and to create programs that will rehabilitate, re-educate and re-socialize juvenile offenders. To keep juvenile offenders from falling behind in their education, the training school offers a full range of academic courses as well as art, sports and music electives, and also vocational training. At the same time, juvenile courts reserve the power of incarcerating the juveniles in this type of correctional institutions (e.g., Milan, 1996). The effectiveness of these schools has been the subject of recent controversy (e.g., Inderbitzin, 2006). The age of training school inmates more closely matched samples of juveniles in prison-based research.

Although, the overall interest in prison bullying research has increased covering full remit of the prison population – adults, young offenders, juveniles, men and women, although of these juveniles and women remain the least researched (Ireland, 2005a), with Ireland and Monaghan (2006) stressing the need for more research in juveniles in correctional institutions. The current study aims to assess the lack of research exploring differences between juvenile males in training school and adult males in prisoners in relation to bullying behavior, whereby both facilities were maximum security correctional institutions.

The focus of prison bullying research has been on adult offenders, especially to men (Ireland, 2011), whereby few studies focus on the differences in bullying behavior in prison among 18–20 year old (young offenders) and 14–17 year old (juveniles) offenders.

At one side, research exploring differences between adults and young prisoners self-reported bullying behavior have been restricted to five studies: two of them exploring bullying behavior across sample of male and female inmates (Ireland, 1999a; 1999b), one examining bullying behavior and attachment and emotional loneliness among males (Ireland & Power, 2004); one exploring bullying and psychological health among males and females (Ledy & O'Connell, 2002); and another (Smith, Pendleton, & Mitchell 2005) concentrated to bullying behavior and prison anti-bullying policy experiences among males. Ireland et al. (1999) conducted a brief review studies and reported a high prevalence rate for self-reported bullying and victimization in young offender institutions compared to adult institutions. In prison settings male youth offenders reported more psychological, physical and verbal bullying than adults (Ireland, 1999a, 1999b; Ireland & Power, 2004); adults did demonstrate a preference for indirect aggression, whereas young offenders demonstrated a preference for direct aggression displaying physical and verbal bullying types towards others.

On the other side, only few studies explored self-reported bullying behavior among juveniles in prison: four studies (Ireland, 2002b, 2005b; Ireland & Archer, 2004, Ireland & Monaghan, 2006) had examined the nature and extent of bullying between young and juvenile male offenders, with focusing on the aggressive traits (Ireland & Archer, 2004), and on the psychological health (Ireland 2005b); one descriptive study explored the perceptions of male adult, young and juvenile prisoners with regards to how bullying was defined (Ireland & Ireland, 2003); and one study compared juvenile, young and adult prisoners within the same dataset (Ireland & Hafiz, 2010).

The prison-based research with regards to adolescents has been descriptive in nature exploring the nature and extent of bullying: Juveniles were found to be more likely to report behaviors indicative of “being bullied physically” than young offenders (Ireland, 2002b; Ireland & Monaghan, 2006), with indicating (Ireland, 2005b; Ireland & Monaghan, 2006) that this extended to psychological, verbal, and overall direct forms of victimization; juveniles were more likely than young offenders to be classified as bully/victims, whereas young offenders were more likely to be classified as not involved than juveniles (Ireland, 2005b; Ireland & Hafiz, 2010), and both juveniles and young offenders reported similar levels of indirect bullying behavior (Ireland, 2002b).

The present study used a self-reported questionnaire to provide a descriptive analysis of the nature and extent of bullying at training school among male adolescents and at prison among male adults, and the aim of the study was to compare the nature and extent of bullying between these two male institutionalized study groups. It was hypothesized that adolescents’ bullying at training school would involve a greater proportion of direct forms than adults’ would; and that adults’ bullying in prison would display a greater proportion of indirect forms than juveniles’ would. It is hoped that this will address the lack of research which examines nature and extent of bullying in training school setting for male juvenile delinquents.

METHOD

Samples

The first sample consists of 105 male adult offenders 21 - 66 years old with average age 33.1 years (SD=9.3) at one of the four maximum security male prisons in Estonia (overall: five prisons and one of them for females) in Estonia. All had been sentenced with an average length of 3.1 years; the combined range of offences included property crimes (43.8%), violent offences (18.9%), drugs offences (11.9%), homicide (9.4%) sex offences (4.6%), criminal damage (3.55%), and other offences (7.9%). 54% were Estonians, 44% Russians and 2% mixed nationality.

The second sample consists of 53 male adolescent offenders (whole sample) 13-17 years old with average age 14.7 years (SD=1.24) at the only maximum security male juvenile training school (the other training school is for girls) in Estonia. All male adolescents at training school had been *incarcerated* with an average length of 1.1 years; the combined range of offences included public order crimes (72.1%), property crimes (36.6%), violent offences (44.2%), drugs offences (49.0%), and other offences (4.5%). 57% were Estonians, 40% Russians and 3% mixed nationality.

The men’s maximum security prison was part of the correctional system, whereas the juvenile training school was part of the educational system. Both institutions had no anti-bullying policies.

Instrument

The self-report questionnaire developed by Ireland and Archer (1996) was used to measure the awareness of bullying in the correctional institution, individual involvement in bullying,

characteristics of bullies and victims, types of bullying, staff and peers intervention, the prevention of bullying and places in the institution where bullying occurred consisting of close end and open end questions. A definition of bullying was given near the start of the questionnaire. Questions about temporal occurrence of bullying (during day and week) in the institution were added into the questionnaire. Additionally, the extent of bullying was measured using the number of inmates who reported themselves as being involved in bullying behavior.

Pretest and Procedure

After approval was received from the prison and training school institutions' internal review boards, an announcement was made on all of the units in both facilities to participate in the study. Before survey research, the Estonian and Russian version of questionnaire was pre-tested in prison and juvenile correctional facility by the authors. Pre-testing was done on a small sample of respondents (N=16) from the target population. After the pilot test respondents were asked a series of questions regarding the survey as well as the process of data collection during the debriefing session.

Participants were invited to *participate voluntarily* and asked to fill in an anonymous questionnaire without being informed of its nature. *The authors conducted questionnaire surveys* in both correctional institutions. The questionnaire was administered in small groups of two or three, with respondents seated in available rooms, at separate corners, facing away from each other. They were asked individually to read the information preceding the questionnaire including definition of bullying and the explanation of the research. The anonymity of questionnaire was stressed. Each respondent was provided with unmarked sealable envelope in which to place their completed questionnaire. Respondents were asked if they had any difficulties in reading and if so the questionnaire was conducted individually and verbally. All defaced, non-completed questionnaires (total 2.4%) were disregarded and not entered into the analysis.

The results were content analyzed and differences assessed through Chi-square or *t*-tests. The overall percentage of agreement between two raters on the descriptive categories of open-ended questions developed after data collection was 92.3% (these data were unsuitable for analyze).

Results

Extent of Bullying

The perceived extent of bullying, based in the Likert scale of 0 (none) to 7 (a lot) showed a mean of 4.08 among adult prisoners and 2.50 among juvenile delinquents, with prisoners responding a significantly higher value than young offenders ($t=4.46$, $p<0.001$).

Number of Inmates Seen or Heard in the Past Week ~~Has Been~~ Being Bullied

Most of the inmates (77% adults and 62% adolescents) reported having seen an inmate being bullied with highest frequency of inmates was seeing 2 – 4 (59% in both institutions).

More inmates in prison (63%) compared with inmates in juvenile training school (44%) have heard about bullying of inmates in the past week ($\chi^2=4.1$; $p<0.05$) with highest frequency of involving of 2 - 4 inmates.

Bullies, Victims and Bully/Victims

The *self-reported prevalence* rates of *bullying*, *victimization*, and *bully/victims* in the prison were accordingly: 21%, 18%, and 17%. In the juvenile training school the rate of bullies was 17%, prevalence of victims 13%, and bully/victims 15%. Overall 56% of inmates were involved in bullying behavior in prison versus 45% in juvenile correctional facility (there were no significant differences between rates between two types of correctional facilities).

About a half of all bullies reported having 2 to 4 occasions of bullying (among adults 52% and youth 55%), and half of victims reported ~~has~~ being a target of bullying 2 to 4 occasions (among adults 54% and youth 57%) during past week. (Henceforward: Subjects offered more than one response across categories.). More than one third (prison: 36%, training school: 40%) of bullies know their victims beforehand, and more than 70% (prison: 71%, training school: 82%) victims know their bully beforehand.

Most common reasons given as to why they bullied included “the victim deserved it”, but differed in some aspects: adults explain bullying more by boredom and with victims’ sex offenders than adolescents (15.8% vs. 0%; $\chi^2=8.9$; $p<0.01$; 49.1% vs. 10.3%; $\chi^2=8.3$; $p<0.01$), and adolescents mentioned more often than adults that victims had low physical power (34.6% vs. 0%; $\chi^2=9.7$; $p<0.00$), whereby about one tenth of inmates had an attitude, that bullying involves all inmates in the institutions (Table 1).

Reasons offered as to why victims felt they had been bullied included being different/minority and older/younger inmates with more attention to reasons connected to boredom or fun for adults (41.7% vs. 10.3%; $\chi^2=9.0$; $p<0.00$), to isolation or rejection for adults (14.6% vs. 3.6%; $\chi^2=5.0$; $p<0.05$), to refusing to comply with bully’s demands for prisoners (12.4% vs. 0%; $\chi^2=5.8$; $p<0.05$), to their offence for prisoners (9.2% vs. 0%; $\chi^2=4.8$; $p<0.05$), and to physical weakness for adolescents (67.9% vs. 12.5%; $\chi^2=12.0$; $p<0.00$) in correctional institutions (Table 2).

Table 1. Overall ranked responses (%) among male adult prisoners and juveniles in training school to the open-ended question “Why they are bullied?”

Category	Adult prison inmates (N=105)	Juvenile delinquents (N=53)
The victim deserved it	14%	27.6%
Victim is sex offenders	15.8%	0%
Boredom/fun	49.1%	9.3%
Those considered of low physical power	0%	34.6%
Bullying involves all	10.5%	10.9%
Those considered of low intelligence	1.8%	6.9%
Minority/differences/not liking	5.3%	3.4%
No real reason	3.5%	8.2%

Table 2. Overall ranked responses (%) among adult prisoners and juvenile offenders in training school to the open-ended question “Why do they get bullied?”

Category	Adult prison inmates (N=105)	Juvenile delinquents (N=53)
Minority/difference	12.4%	13.7%
Older/younger inmates	8.1%	10.7%
Boredom/fun	36.7%	3.5%
Refusing to comply with bully's demands	12.4%	0%
Isolated/rejected	14.6%	3.6%
Because of their offence	9.2%	0%
Bully wishes to assert power/physical weakness of victim	9.5	67.9%
Victims are easy targets	2.1%	3.6%

Who Was Bullied

Adults in prison were significantly more likely than juveniles in training school to suggest sex offenders ($\chi^2=12.2$; $p<0.00$), and adolescents more likely than adults the physical weakness ($\chi^2=12.4$; $p<0.00$) younger inmates ($\chi^2=5.4$; $p<0.05$), whereby both study groups viewed victims as vulnerable and introvert, as different from others inmates (mentally, socially, nationally) with little connections with peers (subculture) network (Table 3).

Table 3. Overall ranked responses (%) among adult prisoners and juvenile offenders in training school to the open-ended question “What sorts of people get bullied here?”

Category	Adult prison inmates (N=105)	Juvenile delinquents (N=53)
Vulnerable, introverts	21.1%	19.4%
Physically weak	14.5%	40.3%
Young inmates	1.6%	13.9%
Sex offenders	19.1%	0%
Those considered of low intelligence	12.5%	6.9%
Minority/difference	6.3%	1.4%
No effective social skills	2.3%	4.3%
All are bullied	6.6%	6.9%
Non-conformists with criminal subculture	9.4%	6.9%
No social support from other peers	3.1%	2.6%
Problem history	1.2%	0%
Staff is bullying	2.3%	0%

Why Inmates Were Bullied

Men in prison were significantly more likely than male youth in youth institution to offer the category “because of their sex offence”, and “boredom”(accordingly: $\chi^2=6.7$, $p<0.00$; $\chi^2=4.7$, $p<0.05$), whereas adolescents were significantly more likely to offer “physically or mentally weak” ($\chi^2=4.9$, $p<0.05$) and the category “victims are easy targets” ($\chi^2=8.6$, $p<0.01$) and then adults, whereby the last category was most characteristic for both study groups (Table 4).

Table 4. Overall ranked responses (%) among adult prisoners and juvenile offenders in training school to the open-ended question “Why do they get bullied?”

<i>Category</i>	<i>Adult prison inmates (N=105)</i>	<i>Juvenile delinquents (N=53)</i>
Victims are easy targets	31.8%	50.7%
Boredom	11.8%	1.6%
Because of their sex offence	11.4%	0%
Physically or mentally weak	4.1%	14.9%
Bully wishes to assert power	9.8%	8.0%
Non-conformists with criminal subculture	9.5%	13.4%
Isolated or rejected	9.1%	11.9%
Belonging to the lower hierarchy	3.2%	1.5%
Unable to look after themselves	3.2%	1.5%
Younger inmates/old inmates	1.4%	4.5%
Bullied by staff	0.9%	0%

Who Was Bullying

Both groups of inmates generally characterized bullies as those persons who wish to assert power, but adolescents more likely than adults ($\chi^2=11.9$, $p<0.00$). Prisoners mentioned more frequently bullying of inmates by staff than juveniles ($\chi^2=5.5$, $p<0.05$) (Table 5).

Table 5. Overall ranked responses (%) among adult prisoners and juvenile offenders in training school to the open-ended question “What sorts of people bully others here?”

<i>Category</i>	<i>Adult prison inmates (N=105)</i>	<i>Juvenile delinquents (N=53)</i>
Bully wishes to assert power	58.9%	85.8%
Staff is bullying	13.0%	0%
Aggressive/violent	10.3%	8.1%
Low intelligence/education	4.1%	0%
Young/old inmates	4.8%	4.1%
All are bullies	2.7%	2.0%
Boredom	6.2%	0%

Types of Bullying

The main common category of bullying in two types of institutions was mainly verbal bullying (about one third of cases) and also in some degree (less than 3%) sexual bullying, but juvenile offenders were significantly more likely than adults to report gossiping ($\chi^2=4.1$, $p<0.05$), intimidation ($\chi^2=13.1$, $p<0.00$), rejecting ($\chi^2=4.2$, $p<0.05$), and ostracising ($\chi^2=4.0$, $p<0.05$), whereby juvenile male offenders report more often than men physical assaults ($\chi^2=23.8$, $p<0.00$) (Table 6).

Table 6. Overall ranked responses (%) among adult prisoners and juvenile offenders in training school to the open-ended question “Describe the type of bullying that takes place in as much detail as possible?”

<i>Category (type of bullying)</i>	<i>Adult prison inmates (N=105)</i>	<i>Juvenile delinquents (N=53)</i>
Verbal (direct)	33.9%	32.9%
Gossiping (indirect)	7.5%	0%
Intimidation (indirect)	20.8%	2.6%
Rejecting (indirect)	9.0%	1.3%
Ostracising (indirect)	6.5%	0%
Physical (direct)	12.9%	56.6%
Sexual (direct)	3.3%	1.3%
Taking things (direct)	6.1%	6.6%

When the categories were conducted into direct and indirect aggression, then adolescents in training school were more likely than adult prisoners to report direct forms of bullying (93.6% vs. 57.1%; $\chi^2=4.0$, $p<0.01$), and prisoner more likely report indirect forms of bullying than youth inmates (42.9% vs. 6.4%; $\chi^2=4.0$, $p<0.01$).

A brief description of the names given to specific acts of bullying by: (1) the prison inmates includes words describing forms of verbal, indirect bullying, and also bullying for fun, and (2) the juvenile offenders describing consists forms of physical bullying using their mother tongue and English synonym, whereby both study groups described specific acts of sexual bullying.

Where Bullying Occurs

The main categories arising from the question “Where do they get bullied?” were “anywhere” (in prison: 25.7% and in juvenile training school: 21.5%) and “out of sight of staff” (in prison: 14.1% and in juvenile institution: 15.2%), and in the yard (prison: 5.6% vs. juvenile institution: 5.6%). Differences between two study groups revealed among three categories: prisoners were significantly more likely than juveniles in training school tended to offer category “living quarters” (accordingly: 45.1% vs. 24.1%; $\chi^2=13.4$, $p<0.00$), and adolescents more frequently than adults reported category “washrooms/toilets” and “classroom” (accordingly: 2.1% vs. 13.7%; $\chi^2=9.4$, $p<0.01$ and 3.3% vs. 24.1%; $\chi^2=14.9$, $p<0.00$).

When Bullying Occurs

Answers to the questions “When does bullying occur during the day in the institution?” were as follows: Morning (significant differences between two study groups with more prevalent results among adolescents compared with adults: accordingly 15.1% vs. 6.4%; $\chi^2=5.3$, $p<0.01$), afternoon (in prison: 32.3% and in juvenile training school: 17.8%), evening (in prison: 38.5% and in training school: 24.7%), and at midnight (more frequently mentioned among adolescents compared with adults: accordingly 2.4% vs. 21.9%; $\chi^2=15.2$, $p<0.00$).

Research results indicated that more prisoners than juveniles reported that bullying occurring in the institution during all days in the week (79.6% vs. 47.8%; $\chi^2=8.4$, $p<0.00$) whereas more juvenile offenders mention significantly more likely that bullying occurs in the institution during working days compared with prisoners’ opinions (10.2% vs. 29.3%; $\chi^2=7.4$, $p<0.00$).

Interventions with Bullying

The majority of inmates (prison: 56%, training school: 62%) stated that other inmates would try to help when bullying is occurring. Nearly one sixth of adult prisoners and adolescents revealed that when someone of inmates is being bullied they try to calm the situation down (accordingly: prison inmates: 14.9% and juvenile delinquents: 13.1%). Also, juveniles in training school were significantly more likely than inmates in prison to say that they try to help the victim unconditionally (accordingly: 57.9% vs. 17%; $\chi^2=13.6$, $p<0.00$) and reported to the help of adult staff members (accordingly: 23.7% vs. 0%; $\chi^2=8.9$, $p<0.001$). Adult prisoners were significantly more likely than juveniles to reveal that they help conditionally: when the victim is friend (29.8% vs. 5.3%; $\chi^2=4.1$; $p<0.05$), when it is useful for them (21.3% vs. 0%; $\chi^2=7.2$, $p<0.01$) or even support the bully (17% vs. 0%; $\chi^2=4.2$, $p<0.05$).

Reasons given as to why other inmates would not help included “non of their business/not want to get involved” (prison: 45.4% and training school: 28.1%), “fear of retaliation” (prison: 39.4% and training school: 50.0%), “the victim usually deserves it” (prison: 9.1% and training school: 6.3%), and “there are many bystanders of bullying” (prison: 6.0% and training school: 15.6%), whereby no significant differences was found.

Staff Intervention

Juvenile offenders in training school were significantly more likely than inmates in prison to say that staff try to intervene when bullying occurs in correctional institution (87.5% vs. 57.9%; $\chi^2=15.4$, $p<0.00$). Most prison inmates and juvenile delinquents stated that staff would intervene by “placing the bully on report on punishment” (prison: 21.7% and training school: 16.7%), “warning/confronting bully” (prison: 37.7% and training school: 29.6%), and “separating the bully and victim” (prison: 20.3% and juvenile training school: 25.9%). Additionally, inmates in prison revealed more likely than juveniles at training school that staff intervention is ineffective (37.7% vs. 0%; $\chi^2=10.4$, $p<0.00$), and juveniles stated two more possibilities for staff intervention: monitoring and talking to the victim (14.8% vs. 0%; $\chi^2=7.6$, $p<0.00$; 13.0% vs. 0%; $\chi^2=4.2$, $p<0.05$).

Reasons given for why staff would not help included: “unaware of the problem” (significant differences between two groups with more prevalent results among adolescents compared with adult inmates accordingly: 93.8% vs. 34.8%; $\chi^2=11.7$, $p<0.00$), “not bothered/don’t care” with frequent answers among prisoners compared with juveniles (45.5% vs. 62.%; $\chi^2=8.8$, $p<0.01$), “indulgent attitude towards bullying” (13.6% vs. 0%), and “can’t really do anything to stop it” (7.1% vs. 0%) with prisoners’ prevalent answers.

To Whom Would an Inmate Advise a Victim of Bullying to Speak to

The two main choices were “another inmate” (prison: 21.8% and training school: 17.8%) and “prison officer or school teacher” (prison: 22.8% and training school: 18.7%), and “nobody” (prison: 2.1% and juvenile institution: 5.0%). Additionally, adolescents in training school revealed more frequently than adult prisoners that they prefer friends and family members (accordingly: 20.8% vs. 1%; $\chi^2=13.6$, $p<0.00$; 19.8% vs. 5.8%; $\chi^2=10.7$, $p<0.00$) as sources of help about bullying issues, and prisoners tended to prefer more frequently specialists in institution than adolescents in training school (40.3% vs. 18.8%; $\chi^2=11.3$, $p<0.00$).

Intervention into Bullying

Most frequent suggestions for intervention of bullying included “nothing” (prison: 23.9% and training school: 37.7%), “more activities and work” (prison: 30.2% and training school: 20.8%), “victim must be more *assertive*” (prison: 10.6% and training school: 13.2%), remove the bullies (prison: 6.9% and training school: 17%), harsher punishment (prison: 7.4% and training school: 11.3%), and increase staff awareness about bullying (prison: 6.3 % and training school: 4.1%). Adult prisoners were more likely than adolescents to suggest “stop mixing prisoners with violent/sex offence history” (17.7% vs. 0%; $\chi^2=13.2$, $p<0.00$).

CONCLUSION

This study provides a descriptive analysis and compares bullying behavior in the male adult prison and in the male juvenile training school, whereby both institutions were maximum security facilities. Male adults in prison and male adolescents in training school were surveyed by self-report questionnaire developed by Ireland and Archer (1996) about the extent of bullying, the frequency the respondent had bullied or been bullied, their perception of bullying, possibilities about prevention and intervention of bullying; and time and place where bullying occurred.

The research aims of the present study were to provide a descriptive analysis of the nature and extent of bullying to examine differences between the male adults in prison and the male adolescents in training school.

Differences between male adolescents in training school and male adult prisoners were found in relation to extent of perceived bullying in these correctional institutions: the perceived extent of bullying was higher in prison compared with juvenile training school. Previous studies support this tendency among juvenile prisoners compared with young offenders (Ireland, 2002b) and among adult prisoners (Ireland & Archer, 1996).

Reports of actually seen of bullying incidences was high (higher than reported among adult prisoners: Ireland & Archer, 1996) - more than 60% of adults and adolescents reported in prison and in training school, whereby the prevalence of hearing of bullying incidents was more frequent in prison compared with juvenile training school setting. Thus, the findings confirm that bullying is a widespread problem not only in male prison, but also in male adolescent training school too, and the key question is not whether, but to what degree.

Overall, 56% of adult males in the prison (not involved 54%), and 45% (not involved 55%) adolescent males in the training school classified, when asked directly, as bullies, victims or bully/victims, with on average 2 to 4 victims each in previous week. Also, approximately the same prevalence of bullying behavior was found among juvenile prisoners (Ireland, 2002b; Ireland & Monaghan, 2006; Leddy & O’Connell, 2002). The overall percentage of self-reported bullying behavior in this study was relatively high, with nearly equal proportion of bullies, victims and bully/victims in both male institutions (prison: 21%, 18%, 17%; training school: 17%, 13%, 15% respectively). Previous studies showed that the proportion of prisoners reporting behaviors indicative of “being bullied” and of “bullying others” were broadly consistent among male young and juvenile offenders (Ireland, 2002b; Ireland & Archer, 2004; Ireland & Monaghan, 2006) and among male young offenders and adult offenders (Ireland & Power, 2004) with regards to classification into these groups; although there was a trend for a

higher proportion of young offenders to be classified as bully/victims than adults (Ireland & Power, 2004), and less proportion of young prisoners to be classified as bully/victims than juveniles in prison (Ireland, 2005b; Ireland & Monaghan, 2006). Regardless of the specific method to classify prisoners into groups bully/victims tending to be the most common and representative of the categories in prison (measured by the behavior indicative of bullying: e. g. Ireland, 2002a; Ireland & Ireland, 2008), in this research direct measurement of bullying was used and differences between proportion of bully/victim category among adult prisoners and juveniles in training school was not revealed.

A particular characteristic of individuals (e.g., vulnerable, introvert) was tended to be viewed as being predisposed to become a victim of bullying among both study groups, as reported previously among adult prisoners (Ireland & Archer, 1996). Additionally, it was revealed that among the male adults in prison, the description of potential victims concurred with reported by Ireland & Archer (1996) and Brookes (1993) featured – sex offenders, but juveniles in training school empathized more frequently the physical weakness of victim and young inmates as victims. Also, Ireland (2002b) revealed that male juveniles were less likely than young offenders in prison to perceive sex offenders as targets for bullying and juveniles were more likely than young offenders to report younger prisoners. The present study confirms these tendencies and specifies it across to settings – male prisoners reported significantly more sex offenders and male juvenile delinquents ~~reported more~~ physically vulnerable and young inmates as potential victims of bullying with general trend for both groups to report victims as vulnerable and introvert characteristics.

Perceptions of causes of victimization included different reasons viewed (1) by juvenile offenders as being predisposed to become victims of bullying as weak (physically or mentally), easy targets and bullies as perpetrators assessing power over victims; and (2) *boredom and particular offence (sex offence)* was behind many incidents of bullying in prison with acknowledgement that bullying may occur as bullying of prison inmates by staff. Thus, juvenile offenders' perceptions about the causes of bullying included the notification of the bullying phenomenon in the area of overt power imbalance, and prisoners perceived the causes of bullying as reflection of specific aspects of lower-stimulation closed prison environment, supporting previous studies (e.g., Ireland & Archer, 1996). As school bullying is defined as subsection of aggressive behavior with repetitiveness and power imbalance (Olweus, 1996), the essence of bullying for juvenile delinquents was analogical for this concept. Additionally, it was revealed that bullying was more probably motivated by boredom in prison than in training school, supporting previous (Spain, 2005) studies among incarcerated youth. Some previous research advocated that bullying in young offenders prison (Spain, 2005) and in juvenile offenders prison (Peterson-Badali, & Koegl, 2002) raveled not only among prisoner, but also between prisoners and staff - bullying of prisoners by staff; and this study support these findings first of all in the male adult prisoners setting.

It was hypothesized that adolescents' bullying at training school would involve a greater proportion of direct forms than adults' would; and that adults' bullying in prison would display a greater proportion of indirect forms than juveniles' would; and these hypotheses were supported.

Overall, the majority of adult prisoners' and juvenile offenders' bullying behavior comprised verbal bullying followed by physical bullying by adolescents in training school and indirect bullying by prisoners. Namely, the types of bullying in prison among men were predominately indirect (gossiping, intimidation, rejection, and ostracizing), corresponding

with previous evidence from male prisoners (e.g., Brookes, 1993; Ireland & Archer, 1996; Turner & Ireland, 2010), whereby male juveniles in training school used predominately physical forms of bullying, corresponding with previous evidence from males in juvenile prisons (Ireland & Monaghan, 2006; Ireland & Hafiz, 2010) and from male young offenders in prison (Ireland, 1999b; Ireland & Power, 2004). The finding that juveniles reported being subjected to more physical bullying than adult offenders is consistent with developmental pathways (Björkqvist, Österman, & Kaukiainen, 1992) suggesting that younger age groups may indeed use more physical aggression. Indirect aggression, on the other hand, carries a higher chance of being caught and the perpetrator risks retribution (Ireland, 2002a), empathizing the possibility that in a prison setting adult prisoners have come to recognize the value of indirect bullying over direct, and employ it. However, male prisoners used more indirect forms of bullying than juveniles in training school did, and both contingents used also direct verbal forms of bullying, whilst sexual bullying was the least common - a pattern also akin with previous prison research (Connell & Farrington, 1996; McGurk & McDougall, 1986, Ireland, 2005b).

In the adult prison and juvenile training school settings the terms connected with bullying (but not the term bullying) were not culturally sensitive, but tended to reflect the prevalent forms of bullying in the detention facility with holding negative connotations. Ireland and Ireland (2003) also asked young and juvenile male prisoners through a self-report questionnaire about their perceptions of bullying and results indicated that bullying could include predominately direct forms of bullying.

Bullying was seen to occur: (1) at locations throughout the correctional institution – mainly out of sight of staff, but relatively more frequently in living areas in prison and more private areas (e. g. bathrooms) in juvenile training school; and (2) during all days a week and all time of day, but relatively more frequently in the morning and midnight during working days among juvenile delinquents. In previous studies young offenders have mentioned more than juveniles that bullying occurred in their living areas in prison (Ireland, 2002b) and much of bullying happened during evening and meal time, on social period in the evening, and at night in the dormitory in young and adult male prisons (Smith, Pendleton, & Mitchell, 2005).

Male inmates of both correctional institutions in this study reported that both they and staff were willing to help victims of bullying, but relatively more (1) prisoners admit that staffs' help was ineffective; self-help was conditional (helping friends, beneficial support), and they even supported the bully; and (2) juvenile offenders tended to believe that staffs' help was effective: monitoring and talking to the victim, and self-help was unconditional. Also, Spain (2005) examining young offenders' attitudes regarding ways for the establishments to combat bullying in prison showed that the majority of participants revealed staffs' failure for supervision.

Regarding interventions, most training school juveniles and prison inmates reported that staff and inmates would intervene – it is consistent with previous studies (Ireland & Archer, 1996; Ireland, 2002b). The reasons why prisoners and juvenile offenders do not intervene were the same as was revealed previously (Ireland & Archer, 1996) in prison context: Fear, detach, blame of victim, but differentiated concerning with perceived reasons of staff nonintervention – more juveniles revealed that staff is unaware of the bullying problem in the institution than prison inmates, and more prisoners than juveniles had accepting attitude toward bullying or even supported bullies. Researchers (Ireland, 2005c) have reported attention on the motivators and functions underlying prison bullying, pointing out also the role of fear.

Two main choices for which an inmate in prison and juvenile training school would advise a victim of bullying to approach were either peer or prison office/school teacher, whereby prisoners prefer more often specialists in prison and juvenile offenders' friends and family members. The last trends were revealed in previous studies (Ireland, 2002b): Juveniles were more likely than young offenders to advise a victim of bullying to speak to their family, a specialist, and a prison officer.

Regarding the possibility of preventing bullying, the most frequent suggestion, as in previous works (Ireland & Archer, 1996I), was "nothing" illustrating attitude that bullying is part of every day's life in prison and in training school too. Parallel with this pessimistic view, there were also suggestions connected with improvement of social environment of both institutions (activation of inmates, punishment of bullies, and increasing of staffs' awareness about bullying), whereby the only prison settings related suggestion was made concerning with separating violent or sex offenders from other inmates. Additionally, previous studies revealed that the most common piece of advice by young or juvenile offenders in prison with reference to how to combat bullying was action on the part of the young offender being victimized (Spain, 2005; Ireland, 2002b). This highlights the importance of taking into account the specific environment (e. g. training school versus prison; male versus female correctional institution) in which the bullying behavior is taking place before applying prevention and intervention.

Like early studies in the research history in the emerging area of prison bullying (Ireland, 2011) employed measures based on school-based definitions that asked offenders directly about their experiences of bullying, using the term "bullying" itself (e.g., Ireland and Archer, 1996), our study is the first one in this area in Estonia. Needless to say that issue of bullying behavior within prison settings has been started now in Estonia and should be continue within adolescent and adult and male and female offenders in prison-based settings as a part of research (Kõiv, 2009) on bullying in diversity settings. Although only descriptive in nature, the present study is the first to offer a valuable insight into bullying behavior that occurs within juvenile training school setting. It demonstrated that, in this setting, bullying is a prevalent phenomenon, which takes various forms and which is worth further investigation. Building on prison-based research among juvenile, young and adult offenders, this paper also highlighted the importance of addressing research across comparison of different age and sex groups to have focus on similar correctional settings. By applying a questionnaire which did use the term bullying, this study has not managed to overcome the methodological difficulties connected with shortcomings leading to possible underestimation of the extent of bullying as mentioned by Ireland (2002b). It is important to note, however, that the current study employed a relatively small sample of adult prisoners and juvenile training school adolescents and thus the conclusions drawn with regard to developmental differences must be done with caution. By examining differences in the nature and extent of male bullying behavior, intervention programs can focus on specific juvenile inmate population in different correctional institutions, included juvenile training schools.

ABSTRACT

Peer victimization occurs when an individual is a repeated target of intentional aggression by one or more peers (Olweus, 1999). Bullying is the intentional repeated aggression directed at a target individual. There is substantial evidence of the negative psychological and health outcomes associated with bullying and peer victimization. In this chapter, we review literature demonstrating the association between bullying/peer victimization and psychological problems (e.g., depression, anxiety, PTSD symptoms). We then consider how peer victimization/bullying impacts the way people think about and process their experiences (particularly their social interactions) as well as how their self-concept is affected. Being bullied affects people's social relationship schemas as well as their cognitive processing. For example, literature indicates that people who are rejected by peers are higher on rejection sensitivity (e.g., anxious expectations about future rejection) and are more likely to engage in dysregulated emotional processing compared to people who are accepted by peers. We also consider how this psychological impact of bullying on cognitions affects an individual's mental health status. Finally, we consider possible avenues for bullying interventions/prevention programs.

INTRODUCTION

Developing and maintaining positive peer relationships predicts healthy emotional and developmental well-being in people of all ages. Positive peer relationships are particularly important in children and adolescents as childhood creates a framework for later thoughts and perceptions of the social world and influences adult behavior. Because most people have an innate desire to create and maintain meaningful interpersonal relationships with others (Baumeister and Leary, 1995), peer victimization can negatively affect an individual. Peer victimization is defined as the perpetual, intentional aggression of a person(s) of higher power directed at someone of lower power (Olweus, 1993). A plethora of problems arise as people try to cope with peer victimization. These coping strategies can manifest as adjustment problems (i.e., internalizing and externalizing problems), symptoms of post-traumatic stress disorder (PTSD), and loneliness. Despite the negative implications of peer victimization, intervention strategies and anti-bullying campaigns in the United States have limited empirical evidence supporting their effectiveness.

We begin this chapter by reviewing the association between peer victimization and these negative outcomes. We then present several cognitive biases and assumptions that may contribute to the association between peer victimization and these negative outcomes and consider the role that social cognition and social information processing play. We conclude by reviewing some of the intervention and prevention strategies and argue that there is a clear and growing need for more effective prevention programs.

PEER VICTIMIZATION AND ADJUSTMENT PROBLEMS

Peer relationships are an important indicator of emotional development and adjustment both concurrently and later in life (e.g., Rigby, 2000; La Greca and Prinstein, 1999). When peer victimization occurs, the social pain experienced by the victim can manifest as adjustment problems (Perren, Ettekal, and Ladd, 2012). Some people who experience peer victimization externalize their problems (e.g., disruptive behavior, hyperactivity, aggressive symptomology) whereas other people internalize their problems (e.g., anxiety, depression, loneliness; Cicchetti and Toth, 1991). In many cases externalizing and internalizing problems predict further peer victimization and/or intensifies emotional pain (Kochenderfer-Ladd and Skinner, 2002). In this section, we consider the association between peer victimization, externalizing problems, internalizing problems, and other negative outcomes related to mental health.

Externalizing Problems

Externalizing problems are characterized by disruptive, oppositional, and/or aggressive behaviors, a lack of regulation and control, attention deficiency, hyperactivity, or impulsivity (Chan et al., 2008; Eisenburg et al., 2000; Olson et al., 1999; Prinstein et al., 2009). Externalizing problems are typical psychopathological responses used to adapt to social situations (Ollendick and King, 1994; Prinstein et al., 2009).

Numerous longitudinal studies have demonstrated that peer rejection is robustly associated with externalizing problems later in life (i.e., delinquency, conduct disorders, attention-deficit/hyperactivity disorder) and that externalizing problems occur most frequently when rejection is experienced repeatedly (Laird et al., 2001; Prinstein et al., 2009). Troop-Gordon and Ladd (2005) ascertained that peer victimization exacerbates social dysfunction in ways that intensify externalizing problems. In addition, externalizing problems typically further compound antisocial behavior or poor social skills that may put people at risk for future peer victimization (Dodge and Pettit, 2003; Fox and Boulton, 2005; Kochenderfer-Ladd and Skinner, 2002).

Internalizing Problems

Peer victimization can also lead to internalizing problems such as depression and anxiety (Ollendick et al., 1994; Zwierzyńska et al., 2013). Individuals who have been indirectly victimized (e.g., gossiped about) are more likely to internalize problems than individuals who have been directly victimized (e.g., hit, called names; Benjet et al., 2010). There is a complex bi-directional dynamic as internalizing problems can be the result of peer victimization and can also be a risk factor for peer victimization (Zwierzyńska et al., 2013).

Depression

One of the most common consequences of peer victimization is depression (Hawker and Boulton, 2000). There is a cognitive triad associated with depression in which depressed individuals have negative perspectives of themselves, their world, and their future (Beck, 1987; Leahy, 2002). Researchers have shown that severe or frequent peer victimization increased the likelihood of having depressive symptoms in adulthood (Gladstone et al., 2006; Lund et al., 2009), although girls who have been both directly and indirectly victimized were more likely than boys to show depressive symptoms concurrently (van der Wal et al., 2003). Zwierzyńska et al.'s (2013) longitudinal study of 3,962 children and parents demonstrated that children who were peer victimized were not only more likely to internalize problems but they were also more likely to show persistent depressive symptoms two years later. Though there is some debate about the direction of influence between peer victimization and depression, Barchia and Bussey (2010) proposed that rumination, school efficacy, and self-efficacy to find support against bullying may mediate the link between peer victimization and depression. In their study of 1,167 school children, Barchia and Bussey (2010) found that individuals who were frequently peer victimized tended to ruminate more than children who were infrequently victimized; this increased rumination predicted depressive symptoms. Children who were bullied were also less likely to believe that school officials and other individuals could provide support and were therefore less likely to seek support which also predicted increased depressive symptoms.

Anxiety

Anxiety is another consequence of peer victimization. Because anxiety can lead to social withdrawal, it can affect the formation of successful interpersonal relationships, lead to disorders or phobias, and be a precursor to negative self-medication tactics like alcohol or substance abuse (La Greca and Mackey, 2007; Moutier and Stein, 1999). Siegel et al. (2009) examined the short-term longitudinal relationships between peer victimization (i.e., overt,

relational, and reputational) and social anxiety in adolescents from November (Time 1) to January (Time 2) of the same school year. They found that all types of peer victimization at Time 1 were associated with social anxiety at Time 2. This relationship was stronger for relational victimization; the more an individual was relationally victimized, the more socially anxious they were. Relational victimization at Time 1 predicted an increase in social anxiety over time but this relationship was stronger for girls than boys. In addition, social anxiety was also a predictor of relational victimization. Anxiety at Time 1 increased the likelihood of being relationally victimized at Time 2.

Again, this pattern of findings suggests that the association between anxiety and peer victimization is bidirectional in nature (La Greca, 2001). Since anxiety, if unchecked, can lead to major depressive disorder, developing intervention techniques might be particularly helpful if employed in anxious victims before depressive symptoms form.

Other Related Negative Outcomes of Peer Victimization

In addition to adjustment problems, being bullied has been associated with other mental health and developmental problems. For example, children (e.g., Idsoe, Dyregrov, and Idsoe, 2012) and adults (e.g., Matthiesen and Einarsen, 2004) who are bullied are more likely to exhibit symptoms of Post-Traumatic Stress Disorder (PTSD) than their counterparts who are not bullied. PTSD was considered to be an anxiety disorder in the DSM-IV-TR (American Psychiatric Association, 2000) and is now listed in the Trauma- and Stressor-Related Disorders section of the DSM-5 (American Psychiatric Association, 2013). PTSD develops after an individual is exposed to an extreme traumatic event (e.g., actual/threatened death, serious injury, sexual violation). Mikkelsen and Einarsen (2002) found that victims of bullying who met all of the diagnostic criteria for PTSD were more likely to report adverse events other than bullying compared to victims of bullying who met some, but not all, of the diagnostic criteria for PTSD.

Although an estimated 29% - 42.6% of victims of bullying meet all diagnostic criteria for PTSD, between 47% - 54.1% of people who were bullied failed to meet A1 diagnostic criterion (i.e., exposure to event(s) that involve actual or threatened death/serious injury or a threat to own or others' physical integrity) but met the other diagnostic criteria for PTSD (Mikkelsen and Einarsen, 2002; Rodríguez-Muñoz et al., 2010). In addition to having more symptoms of PTSD, people who were bullied at work had more negative views of themselves, others, and the world compared to those who were not bullied.

Loneliness is also associated with peer victimization. Loneliness is the feeling experienced when an individual's current peer relationships are thought to be less than what the individual feels they should be (Peplau and Perlman, 1982). Loneliness is predicted by the *perception* of relationship quality rather than the actual quality of relationships (Peplau and Perlman, 1982). The size of the social group is not important, but lower quality friendships are more likely to be associated with feelings of loneliness than are higher quality friendships (Jones, 1982; Parker and Asher, 1993). According to Kochenderfer-Ladd and Wardrop's (2001) longitudinal study of elementary school children, when children were bullied their loneliness increased and social satisfaction decreased over time.

Even children who made the transition from victim to nonvictim did not see a significant decrease in their feelings of loneliness or an increase in their social satisfaction over time.

Individuals who were chronically lonely were more likely to have trouble in school or become a delinquent during childhood than those who were not lonely (Brennan, 1982).

Although teachers may attempt to intervene to stop bullying, these interventions are not always perceived as effective and may contribute to children's prolonged feelings of loneliness (Berguno et al., 2004). Loneliness can also be a precursor to a number of psychiatric disorders including Social Anxiety Disorder and Major Depression (American Psychiatric Association, 2000). In addition to increased loneliness, people who are bullied are also more likely to have more suicidal thoughts (Klomek et al., 2008; Rigby and Slee, 1999) and suicide attempts (Hinduja and Patchin, 2010) compared to people who bully others and those who are not bullied.

As briefly reviewed in this section, the association between being bullied and adjustment problems and other negative outcomes has been robustly demonstrated. Moreover, this association is bidirectional such that being bullied predicts further adjustment problems and negative outcomes which in turn is a risk factor for future peer victimization. We suggest that this cyclical relationship is difficult to break, in part, due to the cognitions associated with being bullied and adjustment problems/poor mental health.

SOCIAL COGNITION AND PEER VICTIMIZATION

In this section, we consider some of the social cognitive biases that may contribute to the cyclical relationship between bullying involvement and negative outcomes. We also review literature demonstrating that social cognition both influences and is affected by social interactions. Social cognition is the study of how people think about others and themselves as well as how they process social situations (Baldwin, 1992; Fiske, 2014, Chapter 3). It is worth noting that social cognition is unlikely to be the only component that affects the link between bullying involvement and adjustment or developmental problems. We focus on social cognition because despite evidence that social cognition affects how we attend to, process, and respond to the general social environment, there is little research examining how being bullied is associated with specific changes in cognitive processing.

Cognitive Biases and Assumptions

People generally want to accurately perceive their world as well as see themselves in a positive and consistent manner (Taylor and Brown, 1988; Taylor and Brown, 1994). However, there are cognitive mechanisms that impede accuracy. These cognitive components may affect the relationship between being bullied and adjustment problems. For example, schemas and scripts affect what information people attend to in the environment and how the information is interpreted (Baldwin, 1992). Schemas are mental representations of objects or categories; scripts are mental representations of situations or events. These schemas and scripts are formed based on a combination of personal experiences and general knowledge. They help people make sense of experiences by creating templates for what to anticipate during a similar experience. Schemas and scripts are especially useful in ambiguous situations to interpret ambiguous information. In the classic "Donald study," Higgins, Rholes, and Jones (1977)

primed participants with words to activate either a positive, adventurous schema or a negative, reckless schema. Participants then read a description of Donald and subsequently rated their perception of Donald. Participants who were primed with positive words rated Donald more positively than participants who were primed with negative words. Because all participants read the same description of Donald, these results suggested that schemas influence what information we attend to and how we interpret the information. Over time and situations, people rely on some schemas/scripts more than others (i.e., chronic accessibility; Breckler, Olson, and Wiggins, 2006, Chapter 3).

The way schemas and scripts affect how people attend to and interpret information in the environment is important because this information is used to make attributions about others' behavior and determine one's own behavior. For example, when responding to ambiguous scenarios that could be interpreted as either aggressive/intended to be hurtful or non-aggressive/not meant to be hurtful, children classified as bully-victims (i.e., were both bullied and bully others) were more likely to blame and be angry with the perpetrator and retaliate than children not involved in bullying (Camodeca et al., 2003). Camodeca and colleagues concluded that bully-victims interpreted the cues within the ambiguous scenario as being malicious/hurtful rather than attributing the perpetrator's actions as being accidental/non-hurtful. In contrast, people who are habitually aggressive tended to attribute ambiguous behavior as being aggressive; this tendency is known as the hostile attribution bias (Fiske, 2014, Chapter 10). In play groups of 8-year-old boys, peer victimization was associated with submissive behavior, hostile attribution bias, and reactive aggression (Schwartz et al., 1998). Boys who were bullied also had negative expectations about the outcomes of aggression and assertion. According to Fiske (2014), this tendency to attribute ambiguous behaviors as being aggressive rather than benign is partially a function of people's daily experiences and the schemas/scripts that are developed.

Classical and operant conditioning may also affect the relationship between being bullied and adjustment problems. Classical conditioning occurs when people learn that two events in the environment are associated. A well-known example of classical conditioning is Pavlov's dogs learning to salivate at the sound of a bell. Operant conditioning occurs when people learn that their behavior elicits consequences (i.e., reward or punishment). For example, a child might learn that hitting a playmate leads to being put in time out whereas sharing with a playmate leads to extra playtime. MacDonald, Borsook, and Spielmann (2011) argued that perceived rewards and punishments within social relationships affect people's behaviors. MacDonald et al. suggested that perceived rewards of social interactions could include anticipating comfortable self-disclosure, making new friends, and developing meaningful connections whereas perceived punishments or risks of social interactions could include social anxiety, the potential of not being liked, and being embarrassed. As people who are bullied begin to anticipate negative outcomes from social interactions, they may begin to overestimate the likelihood of further negative outcomes (e.g., rejection) and underestimate the positive outcomes (e.g., acceptance; MacDonald, Borsook, and Spielmann, 2011). Indeed, Storch and Masia-Warner (2004) found that being bullied was correlated with fear of negative evaluation as well as social avoidance and loneliness. In contrast, people who bullied others felt more secure and less anxious when bullying (Batsche and Knoff, 1994). Bullying behaviors are often reinforced through achieving goals (e.g., controlling others, gaining power) or removing threats from others (Batsche and Knoff, 1994; Vaillancourt, Hymel, and McDougall, 2003).

Dual Cognitive Processing Systems and Social Information Processing

There is consensus within the cognitive psychology field that at least two cognitive processing systems exist (Evans, 2008). The rational cognitive processing system (also referred to as the controlled, systematic, or analytic system) is characterized by reason and logic. Processing within this system is conscious, analytical, relatively slow, and effortful (Evans, 2008; Pacini and Epstein, 1999). In contrast, the experiential cognitive processing system (also referred to as the automatic, heuristic, or intuitive system) is characterized by automatic and instinctual responses. Processing within this system is unconscious, intuitive, relatively rapid, implicit, and low effort (Evans, 2008; Pacini and Epstein, 1999). These two processing systems typically operate in a synchronous manner to allow people to adjust to social situations.

In order to understand how people use and process information from social experiences to determine behavioral responses, Crick and Dodge (1994) proposed that social information processing consisted of six steps: (1) encoding the cues from the social interaction, (2) interpreting the cues, (3) clarifying goals, (4) accessing or constructing a response, (5) deciding how to respond, and (6) executing the behavioral response. Crick and Dodge's model accounted for past experiences, social schemas, and knowledge of social rules affecting each step of social processing. Although Crick and Dodge's model is comprised of specific discrete steps in social information processing, much of the research examining how social information is processed during negative social interactions includes multiple steps rather than specific discrete steps. Below we review some of this literature to provide a brief overview of how negative social experiences such as being bullied affect cognitive processing (Bernstein et al., 2008).

Attention to and Interpretation of Social Information

Attention to social cues increases after being socially rejected (Bernstein et al., 2008) and may be an attempt to successfully reestablish social connections (Hess and Pickett, 2010). Individuals who are periodically bullied or excluded from a group were better at interpreting the non-verbal cues of others. For example, people who were periodically bullied were more accurate in assessing facial expressions and emotions compared to people who were not periodically bullied (Bernstein et al., 2010). This heightened awareness of social surroundings suggests that a change in rational cognitive processing may occur due to an individual's willingness to adapt to social situations in order to cope with social rejection. Increased attention to social cues may also be due to an increase in depressive symptoms (which have been shown to reduce rational processing) that often accompanies peer victimization (Gibb et al., 2004; Pacini and Epstein, 1999). Individual differences in rejection sensitivity may also affect how people attend to and process social information, especially in situations where rejection cues are ambiguous. Individuals high on rejection sensitivity anxiously expect, readily perceive, and overreact to rejection (Downey, Feldman, Khuri, and Friedman, 1994; Feldman and Downey, 1994). For example, Downey and Feldman (1996) manipulated feedback provided to participants following a 10-minute interaction with a confederate (participants were expecting a subsequent 5-minute interaction; Study 2). Participants were either told that the confederate did not want to continue the study (i.e., ambiguous rejection information) or that there was not enough time for the second interaction. Individuals high on rejection sensitivity were more likely to report higher levels of perceived rejection compared to people low on rejection sensitivity. Zimmer-Gembeck et al. (2013) also demonstrated that adolescents who

overestimated their peer victimization (i.e., had higher self-reported peer victimization compared to their peer-reported peer victimization) were high on rejection sensitivity.

Moreover, the specific types of attributions people make regarding why they are bullied affect the strategies used to cope with being bullied. For example, children who attributed being bullied to their race were less likely to seek out support from friends, whereas boys, but not girls, who attributed being bullied to not being cool were likely to seek support from friends (Visconti, Sechler, and Kockenderfer-Ladd, 2013). In addition, children who attributed being bullied to their own behavior were less likely to attempt to problem solve and more likely to retaliate. The variation in attributions made in response to bullying suggests that emotional cues can trigger a specific set of behavioral response tendencies that differ among individuals (Gross and John, 2003).

Forming and Clarifying Social Goals

In addition to attributions about the intent of behaviors, the broader social goals people have are related to involvement in bullying and how people behave during ambiguous and negative social interactions. For example, Smalley and Banerjee (2013) found that low concern about getting along with a perpetrator in ambiguous scenarios was related to physical and relational bullying (even after accounting for affect and attributions). Avoiding the perpetrator was associated with both relational bullying and physical victimization; in addition, submissiveness predicted relational victimization. Rudolph et al. (2011) found that children's broader social goals predicted situation-specific goals. Children who wanted to develop harmonious, high-quality relationships were more likely to report adaptive responses (e.g., want to cooperate and reduce conflict, less likely to want to retaliate and control others), whereas children who wanted to obtain positive judgments were more likely to have maladaptive responses (e.g., less likely to want to cooperate, more likely to want to retaliate and control others).

Behavioral Responses

Involvement in bullying also affects behavioral responses. Researchers have demonstrated that children who are repeatedly bullied often have inappropriate and/or ineffective responses to negative social situations (Crick and Dodge, 1996; Olweus, 1978; Rosen et al., 2007; Schwartz et al., 1993; Schwartz et al., 2001). For example, peer victimized children can engage in behaviors that elicit further victimization (e.g., submissive behaviors, angry but ineffectual retaliation, aggression; Perry et al., 2001; Perry et al., 1990). Boys who responded to provocation by fighting back were more likely to continue to be bullied, whereas boys who had a friend help during provocation were less likely to continue to be bullied (Kochenderfer and Ladd, 1997). In a hypothetical provocative scenario, Camodeca et al. (2003) examined how children responded to situations that clearly involved a perpetrator being intentionally aggressive to a child. Children who were bullied and who bullied others responded in less assertive ways than children who were not involved in bullying (however, no differences were found in use of aggression, help, avoidance, or irrelevant strategies). There is also evidence that negative self-views predicted social disengagement which in turn predicted interpersonal stress, more negative self-views, and social disengagement (Caldwell, Rudolph, Troop-Gordon, and Kim, 2004). Another common behavioral response, especially among girls, is co-rumination. Co-rumination occurs when two friends repetitively and excessively discuss problems and negative moods (Rose, 2002; Rose, Carlson, and Waller, 2007). Co-rumination is both a

protective measure against and a risk factor for adjustment problems. On one hand, co-rumination predicted increased satisfaction in friendships and higher perceived friendship quality. On the other hand, it predicted more symptoms of depression and anxiety, particularly in girls (Rose, Carlson, and Waller, 2007; Stone, Hankin, Gibb, and Abela, 2011). In boys, co-rumination appeared to be indicative of symptoms of depression and anxiety but did not increase these symptoms. Moreover, co-rumination (but not normal self-disclosure of problems) mediated the spread of internalizing problems between friends (Schwartz-Mette and Rose, 2012). Rumination, defined as repetitively thinking about one's negative mood (Smith and Alloy, 2009), is also associated with negative outcomes. For example, rumination predicts future peer victimization, particularly among adolescents who have high levels of depression (Shapero et al., 2013) and is considered to be a risk factor for depression (Erdur-Baker, 2009; Smith and Alloy, 2009).

As reviewed in the above sections, the robust association between peer victimization and negative outcomes is well documented. Given the number of students who are either the recipients or perpetrators of bullying and the negative coping mechanisms employed when individuals are confronted with peer victimization, the next step is to understand and implement systems that can potentially offset the negative consequences.

BULLYING PREVENTION STRATEGIES

Over the last 20 years bullying prevention research has been slow to accumulate in the United States, whereas in Europe, Australia, and Canada, intervention innovation has been addressed for several decades (Swearer, Espelage, and Napolitano, 2009). Despite the large body of work on the description and analysis of bullying issues in many different social contexts, the United States has only recently accumulated enough empirical research to effectively evaluate these US based programs. These evaluations have a potential impact on public policy making and educational programming decisions. However, sound social structures for bullying prevention/intervention are scarce. Even though various state laws have provided some structure to prevent bullying and protect children, each state addresses bullying differently, so uniform policies have not been adopted throughout the education system. This lack of uniform policy leaves huge gaps in services provided for many children involved in bullying across the United States. As a result, many individual schools have been left to create programs without clear guidelines of what to do. Moreover, there are some specific factors that may actually increase bullying in the school environment (Clarke and Kiselica, 1997).

For example, inadequate staffing promotes less than optimal supervision during recreational and instructional periods and prevents adequate monitoring of student behaviors across the school campus. Many schools are very large and the physical structure of the school can contribute to poor monitoring of student behaviors. This is not to suggest that bullying is exclusively a product of large schools and classes, as this hypothesis is not supported by empirical data (e.g., Olweus, 2003). Some schools may actually encourage bullying and violence when they fail to acknowledge that bullying, victimization, and aggression are potential problems. The attitudes and behaviors of principals and teachers are crucial in determining the bullying behaviors that manifest within the school environment (Olweus, 2003). One of the best predictors of implementing school based anti-bullying programs has

been the active involvement of teachers as the key agents of change within the school setting (Kallestad and Olweus, 2003). The following section explores a range of evaluated programs and research that provides a glimpse of potential interventions for different social situations. The programs discussed here focus on children in school, because schools act as a microcosm of the larger social framework and are training grounds of social norm development and future behaviors.

Background of Intervention Programs

In the 1970's as a response to increasing societal concerns over bullying problems among school children, Norway introduced the first large scale anti-bullying program. This program was followed by a nation-wide intensive program known as the Olweus Bullying Prevention Program (OBPP) which was implemented and evaluated in the early 1990's (Olweus, 1991). The OBPP is a long term, system-wide program that focuses on change in four key areas of children's lives: the individual level, the classroom level, the school level, and the community level. It builds on principles derived from research on development and identification of problem behaviors, especially aggressive behaviors. The objective of the OBPP program is to substantially reduce, if not eliminate, existing bully/victim issues in and outside the school setting, prevent the development of new bully/victim problems, and improve peer relations among bullies and victims. Rather than concentrating on changing behavior at any one specific level to accomplish these objectives, the criteria focuses on restructuring the social environment. In other words, focusing on protecting the victim only and/or punishing the bully only is not seen as an efficient or effective approach to dealing with bullying issues. The OBPP philosophy includes creating a school (and ideally, a home) environment characterized by warmth, positive interest, and involvement with adults; firm limits on unacceptable behavior; consistent application of non-punitive, non-physical sanctions for unacceptable behavior or violations of rules; and adults who act as authorities and positive role models (Olweus, 1993; 1999; 2004; Olweus and Limber, 2010). By creating specific measures for classroom use and beyond, these concepts have been assessed in multiple ways at the school, classroom, and individual level. The core components of the OBPP include: a) school-level components (e.g., establishing an bullying prevention committee, introduce clear anti-bullying rules, and train committee and staff members), b) individual-level components (e.g., hold meetings with parents of involved children, supervise students' activities, intervene on the spot when bullying occurs, c) classroom-level components (e.g., post and enforce school-wide rules against bullying, hold regular class meetings, and d) community-level components (e.g., help to spread anti-bullying messages and principles of best practice in the community) (Olweus Bullying Prevention Program violencepreventionworks.org, 2014).

The success of these types of programs hinges on restructuring social environments so that opportunity and reward structures for bullying are disrupted (e.g., less prestige or peer support for maintaining negative social behaviors; Olweus, 1992). The OBPP program initially evaluated 2,500 boys and girls in multiple schools and found dramatic reductions in bully/victims problem behaviors by over 50%, (at 20 months after interventions) along with reductions in several anti-social behaviors. School life satisfaction among students increased and overall classroom social climate improved. The OBPP has been tested and refined for over 35 years and has provided a blueprint for anti-bullying programs in other countries, including

the United States and has been adapted and implemented in schools, the workplace, and senior living institutions (Olweus, 1993, 1999).

The Sheffield Study

Based on the OBPP philosophy of creating a whole-school policy approach on bullying, the Sheffield Study conducted in the United Kingdom in 1994 found some success in reducing reports of both bullying and being bullied (Smith, 1997). The program was tailored to individual school needs but laid out clear directions from the top level supervision all the way through to individual student and staff levels. Additional measures included reconfiguring playgrounds to facilitate improved staff supervision where required; using videos, stories and drama to instill an anti-bullying ethos across the school; and providing assertiveness training for victims and tolerance training for bullies. Smith and colleagues (1997) assessed 27 different schools (23 intervention groups, 4 control groups, approximately 8,380 students) and after two years found a 12% decrease in bullying behaviors both at elementary and secondary school levels and a 14% increase in the control schools.

KiVa Program

The KiVa program was designed and developed in Finland in the 1990's to combat growing concerns for the ramifications of bullying even for those who are not directly involved in bullying scenarios (e.g., bystanders or victims' friends) (Salmivalli, Kärnä, and Poskiparta, 2011). As the researchers behind this program development considered bullying a group phenomenon, the program employed a multi-faceted approach to reduce bullying behaviors (Salmivalli et al., 2011). The KiVa anti-bullying program became nationalized in Finland in 2009 and currently about 2700 schools implement it. They utilize student lessons such as discussion, video films, and exercises in dyads. For secondary school children they also include visual learning tools such as video games involving bullying and an Internet forum (KiVa Street) aimed at changing students' attitudes and ultimately preventing bullying. Program evaluation involved studies of different grades and different types of bullying/ victimization behaviors. Researchers found significant reduction in bullying and adjustment problems among perpetrators and targets and reduced negative behaviors in bystanders (Salmivalli, et al., 2011; Williford, Boulton, Noland, Kärnä, Little, and Salmivalli, 2012). As this program took a whole-school approach the researchers concluded that those teachers and schools who were more involved in the program gained more in terms of reducing victimization overall. Due to the program's ongoing success, it has been translated into several different languages, and evaluation and studies of KiVa based programs are ongoing in the United States.

Safety Training

In the United States one particular study found that providing *safety skill training* to third grade students elevated their knowledge of recognizing and increasing their awareness of bullying behaviors and how to prevent being a target and a potential perpetrator of bullying

later on (Kid Power Safety Report, 2011). In programs targeting safety skill training, the main themes focus on building self-confidence and self-esteem among children. Children participate in multiple activities to teach positive, practical, and effective ways to deal with personal safety situations including abuse, abduction, and bullying. Some of the core concepts of the programs include how to set clear and appropriate boundaries; how to advocate for oneself and others; how to act aware, remain calm and confident to help prevent being chosen as a victim; how to take charge of a situation if it becomes threatening or dangerous; how to effectively get help and persist in getting help when needed; how to stop unwanted teasing and touching; and how to create effective safety plans anywhere one goes (Kid Power Safety Report, 2011).

The initial study was conducted with 238 third graders from 14 different elementary schools throughout Santa Cruz, California in 2010. From initial pretest to a 3 month follow up, the study demonstrated that over 31% of students who received safety training had improved safety knowledge versus a control group who did not receive training. These training programs have gained popularity as the core concepts included can be applied in many different social settings.

Kid Power Personal Safety Skills Project of Colorado Springs (2010), an affiliate of Kid Power International, conducted a similar study to evaluate whether a safety training program would be effective in reducing and/or preventing bullying and abuse of developmentally disabled children from K-12 grades over a 3 year period. They concluded that in general, students, parents, and teachers demonstrated greater knowledge of skills relating to personal safety that could be used in multiple settings. By empowering children with revised schemas and scripts of how to behave appropriately, the Kid Power studies have provided evidence that practical school-based safety training programs can enhance resiliency in individuals and groups when dealing with aversive situations.

Steps to Respect Bullying Prevention Program (STR)

Steps to Respect (STR: Committee for Children, 2005) is a school wide bullying prevention program in the United States. First the school administration assesses the bullying/victimization policies and procedures of the school, then *all* adults within the school workforce (including staff from outside the classroom e.g., bus drivers and cafeteria workers) are trained to recognize and deal with bullying when it arises (Committee for Children, 2005).

Classroom instruction includes multiple tools for identifying, coping with, and doing something about bullying when/if it occurs. An initial review of the STR program reported a 25% reduction in bullying behaviors and a 31% reduction over a two year period (Frey et al., 2005, 2009). Recently Brown et al. (2011) evaluated the Steps To Respect bullying prevention program and corroborated this program's positive effects on reducing bullying behaviors and improving school social climate within one year of implementation, and teachers reported students were 33% less likely to engage in bullying behaviors than those who did not receive the training.

Multimodal Training

In addition to school and general safety training programs it may also be important to recognize when children are involved in family disruptions. For example, adolescents with

divorced parents exhibit higher levels of risky and aggressive behaviors including, but not limited to, bullying (World Health Organization: WHO, 2010). Also, internalizing behaviors such as depression can be a risk factor for becoming a victim of aggression and bullying (Williams, Chambers, Logan, and Robinson, 1996; Williford et al., 2011, 2012). The WHO has emphasized interventions for both parents and children in divorce settings to teach cognitive coping skills, anger control, problem solving, communication skills, and identification and expression of emotions, which in turn fosters social support, and reduces feelings of isolation and loneliness. These factors can often influence positive mental health and reduce risk factors of emotional and behavioral problems. Research has found that these programs assist with reduced depression and behavioral problems one year later (Wolchik et al., 2002). The Good Behavior Game that promotes positive behavior and rule compliance in the classroom showed significant reductions in aggressive behaviors up to five years after the intervention (Kellam, Rebok, Ialongo, and Mayer, 1994). Other programs such as I Can Problem Solve (Shure, 1997) include measures to provide children with cognitive skills such as listening, empathy, interpersonal problem solving, and anger management. These types of programs have improved behaviors for up to one year post intervention. The Child Development Project (Battistich, Schaps, Watson, and Solomon, 1996) provides both children and caregivers with improved behavioral skills to effectively develop prosocial behaviors and has been shown to reduce aggressive behaviors, including bullying, in the school setting.

Youth Matters Prevention Program (YM)

There is substantial evidence that bullying behaviors continue from elementary school to middle school, with some researchers finding stable patterns across the transition (Scholte, Engels, Overbeck, de Kemp, and Haselager, 2007). Conversely, other researchers have found a decrease during the latter two years of elementary school and then a fluctuation throughout the middle school years (Nylund, Bellmore, Nishina and Graham, 2007; Schäfer, Korn, Brodbeck, Wolke and Schulz, 2005; Williford, Brisson, Bender, Jenson, and Forrest-Bank, 2011). Youth Matters is a school-based bullying prevention program that builds training modules into the curriculum with interactive instruction to teach upper elementary school students skills for dealing with bullying in and out of school.

By developing important social competency skills and resistance to bullying techniques, YM emphasizes the negative impact of bullying behaviors while attempting to strengthen peer and social norms against them (Jenson and Dieterich, 2007). One evaluation of the program assessed the transitional bullying effects on students in grades 4-6 and found children involved in bullying did indeed show positive effects of the YM program especially in the first year of intervention (grade 4) and during the first year of middle school (grade 6) (Jensen, Brisson, Bender, and Williford, 2013). Anti-bullying programs may be particularly effective during the latter years of elementary school by providing children with more information and tools to reduce aggression and bullying as they transition into very diverse and often overwhelming school and peer environments.

What the Evidence Suggests

In 2008, Merrell, Gueldner, Ross, and Isava conducted an exploratory meta-analysis of a variety of intervention programs from Europe and the United States spanning a 25 year period. Overall, they found very weak effect sizes for successful bullying interventions suggesting that these programs are more likely to influence knowledge, attitudes, and perceptions rather than specific bullying behaviors. Recently, Ttofi and Farrington (2011) conducted a meta-analysis on the effectiveness of 53 different international school based programs aimed at reducing bullying among children from kindergarten to high school. Again, the results provide a mixed picture on the success of many anti-bullying programs. Overall, Ttofi and Farrington concluded that on average bullying decreased by 20 - 23% with successful programs. The effects were highest in age cohort designs and lowest in randomized experiments (potentially due to validity problems).

A continued dilemma exists over what works and why. Since this research is difficult to conduct and compare due to the vast differences among education systems, there will be a continued challenge to find, evaluate, and implement solid programs that make a difference in the bullying phenomenon. However, the overarching message suggested is that school based anti-bullying programs can be effective depending on the intensity, duration, and types of elements they engage. Ttofi and Farrington concluded that programs influenced by Dan Olweus were the most successful. Those that were more intensive programs that included different social groups such as meetings with parents, improved playground supervision, and firm, consistent disciplinary methods were associated with decreased bullying. Conversely, work with peers (such as peer mentoring, peer mediation and encouraging bystander intervention) was associated with an increase in bullying behaviors.

Bullying is increasingly being considered as a group process that is enabled by many individuals in addition to the specific victims and perpetrators (e.g., Craig, Pepler, and Blais, 2007) and highlights the need for adults to support students in dealing with ongoing bullying issues. As a response, more holistic intervention programs are being considered and implemented. The whole-school approach seems to be drawing more attention, but in the United States one still has to consider the vast cultural, socioeconomic, and ideological differences that exist across the nation – a one size fits all approach will not likely be successful if planners, policymakers, and education decision makers do not recognize these individual differences and tailor programs accordingly (Smith, Schneider, Smith, and Ananiado, 2004).

However, a consistent factor across successful programs is effective and sufficient training of adults who are responsible for initiating and carrying out bullying prevention programs. Any substantial success with anti-bullying programs requires strong consistency and conviction of implementation from the administration all the way through the school environment to bus drivers and caretakers (Durlak and DuPre, 2008; Low, Van Ryzin, Brown, Smith, and Haggerty, 2013). In sum, programs that approach bullying prevention comprehensively while still acknowledging the unique needs of individuals in differing environments are the most effective (Clark and Kiselica, 1997; Espelage and Swearer, 2003; Olweus, 1991). Without full understanding, cooperation, and oversight from all involved, these programs will reap only moderate - if any - results at reducing or eliminating the bullying behaviors that exist in the school and beyond.

CONCLUSION

As we have documented, there are multiple psychological and cognitive factors affecting children's and adults' socialization when exposed to peer victimization. Those individuals who are left to manage such aversive situations on their own may be prone to mental health issues later in life including anxiety, depression, and suicide ideation. It is not only important to recognize these potential issues but also to determine best practices for reducing or eliminating the effects. Comprehensive and consistent interference in environments that support bullying is required, and strong support of those individuals who are both recipients and perpetrators are key factors in reducing or eliminating bullying behaviors.

Chapter 53

BULLYING AMONG MALE ATHLETES: A CONTEXTUAL EXAMINATION

***Jesse A. Steinfeldt*, PhD, Nicole T. Gabana, MS
and Matthew D. Powless, MS***

Indiana University-Bloomington, Bloomington, IN, US

ABSTRACT

As witnessed in popular media, reports of violence and aggression-both on and off the field-is often associated with athletes such as football players. The emphasis on these reports creates a skewed perception of male athletes, and subsequently the non-violent behavior of countless other male athletes is often discounted and ignored. Nonetheless, there is evidence to suggest that male athletes may be more likely to engage in violence than their non-athlete male peers (Kreager, 2007; Messner, and Sabo, 1994; Mutz, 2012). Research aimed at studying this phenomenon has suggested that there is, “a continuum of physical contact and masculinity whereby highly masculinized contact sports increase the risks of violence” (Kraeger, 2007, p. 717). This raises the question: Are boys who participate in certain sports being taught to be violent (e.g., Kotler, 2008)? After critically examining the theories and research addressing this question, in this chapter we will look at the societal stereotype of the “jock bully” as it appears in both popular culture and academic writings. We will then use this psychologically-oriented lens to examine the 2013 Miami Dolphins controversy involving Jonathan Martin and Richie Incognito, where we will apply relevant literature on bullying and masculinity. Lastly, we will discuss future implications for research and clinical work. Prevention is the most desirable form of intervention and future research should therefore assess the effectiveness of violence and abuse prevention initiatives (Stirling, 2008). Professionals working in school, athletic, and occupational settings can use the information in this chapter to inform their efforts to create an environment that can address bullying dynamics.

INTRODUCTION

The dynamic of violence and bullying among male athletes is not only a relevant topic of interest in the psychological study of masculinity and sport, but this topic is also omnipresent in contemporary society. Media reports of male athletes engaging in violence often capture the attention of the viewing audience (Associated Press, 2007; Associated Press, 2012; Smith, 2014). However, these reports represent the minority experience of most athletes—the stories about the myriad of male athletes who do not engage in violent acts do not readily make the front pages. Subsequently, society is left with a skewed perspective, but the question remains: are male athletes more violent than non-athletes?

While there are more non-violent male athletes than violent male athletes, there is some evidence to suggest that male athletes might be more likely to engage in violent acts in relation to men who don't play organized sports (Kreager, 2007; Messner, and Sabo, 1994; Mutz, 2012). Mutz (2012) found that, when compared to their non-athlete male peers, male adolescents in certain sports (i.e., combat sports, bodybuilding activities) engaged in more physically violent acts and more readily endorsed violence beliefs. Specifically, Kreager (2007) reported that male athletes who participate in contact sports (e.g., football, wrestling) were more likely to engage in violent acts, with high school football players being 40% more likely to get in a serious fight when compared to their non-athlete peers. In sum, Kreager purported that there exists, “a continuum of physical contact and masculinity whereby highly masculinized contact sports increase the risks of violence” (2007, p. 717).

While these studies do not present a definitive answer to the original question (are male athletes more violent than non-athletes?), they do raise a related sub-question: Are boys who participate in certain sports being taught to be violent (e.g., Kotler, 2008)? However, this is a nuanced and complicated issue that requires critical thought and examination. Rather than arrive at the oversimplified (and potentially inaccurate) explanation that sports like football make boys more violent, a critical analysis of this issue should be guided by multiple perspectives, most notably the notion of a) instrumental aggression and b) self-selection.

In and of itself, football is a place where young boys are socialized to learn values and behaviors (e.g., competition, toughness, winning-at-all costs) that are considered to be socially desirable aspects of masculinity (Messner, 1996; Steinfeldt and Steinfeldt, 2012). Specifically, contact sports like football encourage and teach instrumental aggression, which allows for a functional need for aggression and even violence to facilitate success on the football field (Messner, 1990, 2002). A football player must hit, dominate, and overpower his opponent in order to be successful. If he does not, that player will be overpowered, hit, and dominated.

As a result, violence can be conceptualized as something that exists within the rules and nature of a sport like football, and boys and young men are rewarded for their successful engagement with functional aggression and violence on the field of play. However, “Reinforcement of masculine gender norms through strict football rituals in team practice creates a behavioral repertoire that may extend to other contexts, with gender norms also informing the interpersonal relationships that athletes form off the field” (Gage, 2008, p. 1016). Thus, it is imperative to teach football players to compartmentalize their aggression and keep it on the field and “between the lines” (e.g., Steinfeldt, Foltz, et al., 2011).

Additionally, the dynamics of self-selection need to be examined in order to shed additional light on this issue, particularly in terms of directionality of influence. Instead of a simplified

explanation of “football teaches boys to be violent” there is value in exploring the types of boys that are attracted to play football. In an early examination of “non conforming males” (e.g., juvenile offenders), Donnelly (1981) identified this self-selection dynamic by concluding that certain types of boys might be drawn to contact sports. For boys who might desire activities that involve risk or other forms of physical aggression, football could provide them with the outlet to physically aggress against other boys, but in a regulated and socially desirable environment. So in sum, through a more contextual examination involving instrumental aggression and self-selection, we can arrive at a more nuanced conclusion than the thought-provoking yet misleading question, “Are sports making our children more violent?” (e.g., Kotler, 2008).

Bullying among Male Athletes

While this nuanced examination provides some contextual understanding of the issue, it doesn’t fully address the reality that some male athletes do engage in violent behaviors off the field (or what we should do about this). While getting into fights off the field is an area of concern, another subset of violence that garners considerable attention in society is bullying. And related to the perception of violent male athletes is the existence of a familiar archetype in American movies and television: the “jock bully” (e.g., Steinfeldt, LaFollette, Vaughan, and Steinfeldt, 2012). This stereotypic representation of a character is often a member of the football team who uses his social and physical influence to harass and bully other students, often peers who are not part of the popular crowd. Movies such as *Revenge of the Nerds* and *The Karate Kid* gave children of the 80s the everlasting “jock bully” images of Ogre and Stan Gable from the Adams College Atoms football team and Johnny Lawrence from the Cobra Kai. Younger folks may resonate more with the image of slushings at the hands of Azimio and Dave Karofsky from the football team in *Glee*. Regardless of preferred genre, these references all conjure up images of characters that are stereotypically represented in popular culture—the stereotype of the jock bully has become firmly entrenched in our minds.

This stereotypic image of the jock has recently emerged in academic writings. Miller (2009) attempted to distinguish the “jock” identity from “athlete” identity, two concepts which have traditionally been interpreted as interchangeable in popular culture. Miller suggested that for athletes who self-identify with this “jock” identity, the link between masculinity and sport-related identity is stronger than for those who self-identify with the “athlete” role. Furthermore, Miller hypothesized that negative behavior associated with athletic status is more commonly attributed to the “jock” identity. This behavior includes problem drinking (Miller et al., 2003), academic misconduct (Miller, Melnick et al., 2005), unsafe sex (Miller, Farrell, Barnes, Melnick, and Sabo, 2005), delinquency (Miller et al., 2007), and interpersonal violence (Miller, Melnick, Farrell, Sabo, and Barnes, 2006). Miller and Hoffman (2009) also found “jock” identity to be related to attempted suicide. Based on these findings, Miller (2009) coined the term “toxic jock” in an attempt to suggest that the strength of identification with this role impacts the athlete’s likelihood of an athlete engaging in negative health-risk behaviors.

Miller, Sabo, et al. (2006) suggested that the “jock” identity is more prominent in high-profile sports which contain some degree of structured physical violence. In such sports, masculinity is emphasized, with football being the epitomic environment for typical “jock” behavior.

Additionally, the “jock” identity was positively associated with status, perceived popularity, institutional support, and overall sport rating (Miller, 2009). Conventional masculine norms such as propensity toward violence, emphasis on risk-taking and winning, a “playboy” attitude toward sexual relationships, and interpersonal dominance were positively predicted by the strength of the “jock” identity. Finally, “jock” identity was significantly related to an ego-focused goal orientation which values the outperformance of competitors by any means possible (Miller, 2009).

Consistent with Miller’s (2009) findings linking social status with this “jock” identity, certain activities (e.g., playing high profile sports) in school settings are linked to high levels of social status (Peguro, 2008). Furthermore, most research on bullying has found that those with high status within peer groups are generally perceived to be the aggressors and bullies (Cillessen and Mayeux, 2007; Pokhrel, Sussman, Black, and Sun, 2010; Prinstein and Cillessen, 2003). Bullying is often used by individuals to either gain status and/or to intimidate others in order to maintain high status, which would explain why bullying is so easily associated with high status groups such as football players (Dijkstra, Cillessen, Lindenberg, and Veenstra, 2010; Caravita Di Blasio and Salmivalli, 2009). These associations occur even before the high school years, when sports begin to take on a greater role for their participants. In a study of adult (i.e., teachers, administrators, counselors) and student perceptions of bullying victimization in a middle school, it was found that adults and students most often identified popular students and athletes as the school bullies (Dranoff, 2008).

Although research has examined the relationship between social status in schools, athletic involvement, and bullying, there has been a dearth of research that has directly investigated specific bullying behaviors and attitudes of athletes. Steinfeldt et al. (2012) conducted a study that directly examined bullying beliefs of high school football players. The authors investigated the role of moral atmosphere (i.e., influence of teammates and their most influential male figure) and the role of adherence to male norms (e.g., *Meanings of Adolescent Masculinity*; Oransky and Fisher, 2009) in the development and potential activation of these bullying beliefs. Results indicated that an adherence to male norms and teammate influence were significantly related to bullying beliefs. The perception of the views of the players’ most influential male (e.g., father, coach, brother) was the strongest predictor of bullying among those boys who reported having engaged in bullying behaviors (after controlling for social desirability).

Beyond these findings, the results also indicated that these high school football players did not report a high degree of involvement with any of the four specific bullying behaviors (i.e., physical; verbal threat; homophobic; relational cyberbullying). In fact, the majority (85%) of high school football players in this study reported that *they have never* (69%) or that *they have rarely* (16%) engaged in any of the bullying behaviors (Steinfeldt et al., 2012). Thus, in spite of prevalent social stereotypes (i.e., “jock bully”), these results indicate that these high school football players do not engage in bullying behaviors at a rate consistent with these societal stereotypes.

Application of Bullying Dynamics to a Case Study

The previous pages of this chapter have been devoted to providing context and perspective on perceptions—both societal and empirical, albeit limitedly so—on the dynamic of bullying among male athletes, particularly those who play the contact sport of football. At this point, we

will provide an example that highlights some of the dynamics of bullying, while also illustrating aspects of bullying that do not fully conform with our emerging understanding of bullying among male athletes.

In 2013 the male “jock bully” stereotype was simultaneously reinforced and challenged. The events surrounding the Miami Dolphins of the NFL provided interesting perspectives on bullying, particularly from the victim’s perspective. Jonathan Martin, an offensive lineman, accused his teammate, Richie Incognito, of bullying. These two men both weigh over 300 pounds and play a physically demanding position (i.e., offensive line) in the “masculinized” (e.g., Richman and Shaffer, 2000) and often violent sport of professional football. While Incognito readily fit the social stereotype of the jock bully, Martin clearly did not fit the profile of a bullying victim: how could a 300-pound professional football player possibly be bullied? The media coverage was intense, and subsequently the incident generated an interesting public dialogue about bullying, power, masculinity, and other related issues, including conversations about “what it means to be a real man” (e.g., Fagan, 2013).

The circumstances surrounding the Martin and Incognito controversy are interesting for a number of reasons, primarily because these events occurred within a culture that exists in a football locker room that is foreign-and even antithetical-to most, if not all, other workplaces. However, a full investigation was ordered and carried out by an impartial investigator, who released the facts in a 144-page report that was filed with the NFL (Wells, Karp, Birenboim, and Brown, 2014), so we can sort through the report and attempt to interpret the situation through a psychologically-oriented lens.

As we present this case study, there are three important factors in this story that relate to relevant literature on bullying and masculinity that contributed to Martin’s withdrawal from professional football. Those factors – which will be the focus of this section – are: a) the victim (i.e., Martin); b) the bully (i.e., Incognito); and c) the social climate within the Dolphins football team and locker room.

THE VICTIM

The victim, Jonathan Martin, was a second year NFL player who was a starting offensive lineman for Miami, but after approximately a year and a half of being bullied and harassed by teammates, decided to leave the Dolphins organization and check himself into a hospital for psychological treatment in the middle of the 2013 NFL season.

Despite being a large, athletic man who successfully played the popular sport of football, Martin reported that he was bullied all through middle school and most of high school (Wells et al., 2014). Evidence has shown that even though bullying victimization decreases as children get older, being a victim of bullying can still be stable across ages for some children (Arseneault, Bowes, and Shakoor, 2009). This was true for Martin as well.

Despite always being large for his age and athletically gifted, Martin was described as being reserved, having low self-esteem, and having low levels of self-confidence, which are often characteristics of children who are bullied (Egan and Perry, 1998). Martin claims that the bullying he experienced in middle school and high school gave him trouble with social adjustment and caused self-diagnosed bouts of depression throughout his teenage and college years (Wells et al., 2014).

While playing professional football for the Dolphins, Martin was harassed primarily by three teammates: Incognito, John Jerry, and Mike Pouncey, with Incognito being the ringleader of the trio. The harassment Martin endured from his teammates came in the form of cyber bullying, verbal bullying, and even physical bullying. The content of what his teammates said and did to verbally harass him included racial slurs, derogatory language, suggestive sexual advances toward members of his family (i.e., sister, mother), homophobic remarks, and slights at Martin's masculinity (Wells et al., 2014).

A graduate of the academically prestigious Stanford University, Martin believes he was bullied because he was different from a lot of other players due to his intellectual interests (i.e., reading books) and quiet nature. This is a valid assumption given that bullying is usually more acceptable when it is directed at someone not a member of the in-group or individuals who are shy or reserved (Duffy and Nesdale, 2009; Ojala and Nesdale, 2004). Martin reported that the bullying by his teammates and his inability to make them stop eventually drove him to depression, resulting in his contemplating suicide on at least two occasions (Wells et al., 2014). Therefore, while Martin may not fit into society's perception of the typical victim of bullying, the effect bullying has had on his mental health is common for victims of bullying. All of the mental health issues Martin says he has faced due to being bullied (i.e., social anxiety, lower self-esteem, depression, hopelessness, suicidal ideation) are consistent with the psychological literature on victims of bullying (Coggan, Bennett, Hooper, and Dickinson, 2003; Dukes, Stein, and Zane, 2009; Espelage and Holt, 2001; Jankauskiene, Kardelis, Sukys, and Kardeliene, 2008; Kim and Leventhal, 2008; Storch, Bagner, Geffken, and Baumeister, 2004).

THE BULLY

We have examined the victim of this situation and now we will turn our attention to the perpetrator: Richie Incognito. According to news reports, Incognito had "run-ins with bullies as a boy" (Wells et al., 2014, p. 59). If that is accurate, Incognito could be grouped into part of a small percentage of victims of bullying who externalize problems, going on to bully others and exhibit violent behaviors later in life (Scholte, Engels, Overbeek, de Kemp, and Haselager, 2007; Arseneault et al., 2009). Previous research on adolescents has shown that those who have been both bullies and victims (a.k.a., bully-victims) exhibit much more conduct problems than either bullies or victims (Juvonen, Graham, and Schuster, 2006). This research fits the profile of Incognito who, as mentioned earlier, fits the stereotypical depiction of the "jock bully."

Before playing for the Dolphins, Incognito was a college football standout at the University of Nebraska, where he would start to develop his "bad boy" reputation. Incognito's college career was filled with behavioral problems on and off the field. Incognito fought on the field, leading to suspensions and even an ejection from a game, was charged with three accounts of assault off the field, and struggled with drug and alcohol issues (i.e., failed drug tests), which he would later admit he abused for a decade (Wells et al., 2014). After a positive drug test for marijuana use and a shoving match with a teammate in the locker room, Incognito was suspended indefinitely from Nebraska's football team. He then transferred to the University of Oregon, but was kicked off their football team after one week for violating team policies. Incognito's alcohol and drug use, conduct problems, and violence off the field were all

problems associated with being a bully, as well as pressure to conform to masculine norms (Curry, 2000; Kreager, 2007; Juvonen et al., 2006; Storch et al., 2004).

Even though Incognito may fit society's idea of what a prototypical bully is, to those in the world of professional football, his behavior can sometimes be perceived as only mildly appropriate, if at all. While football teaches instrumental aggression to succeed, Incognito has often been excessive with his aggression and unable to keep it "between the lines." Before the Dolphins, Incognito played for the St. Louis Rams for five seasons from 2005-2009. In those five seasons, he played 44 regular season games in which he committed 38 penalties, 7 of which were for unnecessary roughness. In 2009, he was deemed the "Dirtiest Player in the NFL," by *The Sporting News* (Wells et al., 2014). Incognito's anti-social behavior extended beyond the football field as well. When interacting with Martin, Incognito reported that he intentionally tried to "break" Martin through verbal harassment (i.e., racial slurs, sexual comments about his mother and sister) on a regular basis, although he claimed this was never meant to cause lasting emotional harm to Martin (Wells et al., 2014). Additionally, Martin claimed that at a Christmas party in 2012, he and Incognito were inoffensively pushing and shoving one another but it escalated quickly when Incognito took off his shirt, tackled Martin onto the sofa, and began punching him in the body and face. This incident humiliated Martin and contributed to the pattern of treatment that led to his departure (Wells et al., 2014).

In addition to being overly aggressive both on and off the field, Incognito has been described by his teammates as "inappropriate," "vulgar," "crazy," "someone who has no filter," and, "the kind of guy who has to be the alpha male" (Wells et al., 2014, p. 65). When considering self-selection dynamics in football, it seems plausible that someone like Incognito would be drawn to the sport because it provides a space where his physically aggressive behavior would be productive, his incessant taunting would be acceptable (i.e., "trash talking"), and his desire to be the alpha male would serve him well in trying to both dominate his opponents and motivate his teammates toward instrumentally aggressive behaviors that can help the team win.

So far we have focused on the characteristics of a stereotypic "jock bully" that aptly describe and fit Richie Incognito, but the flip side of that stereotype provides a question that still remains: How could another physically imposing, 300 pound man---who had also been socialized in the same context of football his whole life--also be the victim of bullying? Part of this answer resides in an analysis of relational power. When Incognito harassed Martin, he was using his relational power to his advantage, which is common in cases of bullying in any workplace (Hodson, Roscigno, and Lopez, 2006). Incognito and Mike Pouncey were regarded as the leaders of the offensive line, if not the entire offense, and even served on the Dolphins' *Leadership Council*, a group of players who serve as representatives to the head coach, Joe Philbin, despite their anti-social behaviors (Wells et al., 2014). Martin was a young player and Incognito was considered to be a superior member of the team to him due to his appointed leadership status. Additionally, there was an incident in which Martin got in a fight with a Dolphins defensive lineman and Incognito came to his defense (Wells et al., 2014). These circumstances placed Incognito in a more powerful position than Martin, leaving Martin to be more vulnerable to bullying. Furthermore, there was a lack of visibility of Incognito's bullying behavior to many of the staff members in the Dolphins organization, and this lack of visibility helps allow bullying behaviors to occur relatively unfettered in the workplace (Hodson et al., 2006).

SOCIAL CLIMATE

An NFL locker room is a workplace, albeit a workplace unlike any other professional venue. Like many other football teams, the Dolphins have a unique locker room culture that is insulated from certain social controls and pressures, which allows for antisocial behavior to occur that would not be allowed elsewhere (Messner, 2002; Wells et al., 2014). While Incognito and other linemen on the Dolphins have acknowledged that their behavior towards Martin and others was harsh (and unacceptable in other places in society), they considered it to be a part of joking and bonding that comes with being on a football team. This aligns with previous research that bullying behavior increases when it is endorsed by group norms and is more acceptable in places where there exists a climate of low level of moral functioning (Duffy and Nesdale, 2009; Gini, 2008; Ojala and Nesdale, 2004; Steinfeldt et al., 2012).

In regard to this climate of low moral functioning, one of the coaches of the Dolphins was reported to have joined players in making homophobic jokes toward another teammate ("Player A" as he is listed in the report; Wells et al., 2014). As mentioned earlier, research has shown that the strongest predictor for bullying behaviors among football players is their perception of whether the most influential male figure in their life (e.g., father, coach) would approve of this bullying behavior (Steinfeldt et al., 2012). These men have been socialized in the culture of football where players respect coaches and even revere them in their position of authority. Therefore, it is likely that the coach's participation in this bullying facilitated and enabled the maintenance of an environment that endorsed norms that allowed bullying behaviors.

Additionally, there existed an accepted cultural norm amongst the Dolphins players for "no snitching." This rule was especially important to the offensive linemen who had a "Judas" code, introduced by the coach who also joined in on the homophobic bullying behaviors. The "Judas" code was created for film sessions to prevent linemen from "snitching" on other linemen. If a lineman missed an assignment and was criticized during a film session by this coach, but then pointed out that the botched play or missed assignment was another lineman's fault, then he would be labeled a "Judas" and have a fine imposed on him by another teammate. With this in mind, Martin refused to seek help out of fear for being labeled a "Judas," (Wells et al., 2014).

The reaction by players to the Martin case was interesting--in fact, many players defended Incognito and chided Martin for not having thick enough skin. Martin violated a code of the locker room by snitching and "not taking care of his business." However, after Martin left the team midseason, several players have since admitted that Incognito's behavior toward Martin and even other players was inappropriate.

One player confided that most players did not intervene when Incognito bullied and harassed Martin or others because they did not want to become the target of harassment themselves. Even Martin participated in making homophobic jokes about another player ("Player A") with Incognito (Wells et al., 2014), likely in an attempt to align with the bully and deflect the harassment that was usually directed his way. This lack of intervention by the other players is consistent with findings in the psychological literature that suggests boys will tease and even bully other boys in order to avoid being victimized themselves (Steinfeldt et al., 2012). Although the verbal abuse that Martin endured was considered to be normal by many Dolphins players, these behaviors were in direct violation of the team's formal anti-harassment policies. In 2013, prior to Martin's departure, the Dolphins players were given a workplace conduct policy that strictly prohibits the type of behavior that occurred.

Additionally, Coach Philbin publicly strived to promote integrity within the Dolphins organization and was found to be completely unaware of either Incognito's behavior or Martin's mental health ailments (Wells et al., 2014). However, consistent with culture of football locker rooms and traditional norms of hegemonic masculinity (e.g., Connell and Messerschmidt, 2005), this bullying behavior (e.g., homophobic slurs, insinuation of having sex with one's mother or sister, chiding one's manhood) can be inappropriately dismissed as "boys just being boys," particularly within the context of a football locker room, a dismissal that can allow bullying behaviors to flourish.

CONCLUSION

In spite of societal misperceptions that a 300-pound male professional football player should be immune to bullying, research has shown that there is almost no demographic which can completely shield someone from becoming a victim of bullying (Dane-Staples, Lieberman, Ratcliff, and Rounds, 2013). Although Martin would have been justified in seeking help, the culture of the Dolphins football team led him to believe that he would be wrong in doing so. Players should not be discouraged to seek professional help when it is needed because, "even the largest, strongest and fleetest person may be driven to despair by bullying, taunting and constant insults," (Wells et al., 2014, p. 140). This incident shows the importance of regulating what is acceptable behavior in a school, locker room, or workplace. Many teams purport to promote a healthy locker room culture, but the regulation of a football locker room is often considered to be the responsibility of the players, which can present a conflict of interest when the bully is in charge.

In sum, if bullying is considered to be, "behavior that is intended to inflict harm or stress, occurs repeatedly over a period time, and involves an inequity of strength or power," (Steinfeldt, LaFollette et al., 2012, p. 341) then it becomes clear that this situation represents an interesting example of bullying. Incognito claims he never intended to cause Martin harm, yet intent does not always equal outcome. Given the unique nature of the football locker room, was this simply a part of football culture that Martin was unable to cope with? Wells et al. (2014) ultimately decided that Incognito's friendship with Martin and the culture of the Dolphins football team did not excuse the harassment directed at Martin. This was a case of bullying, even if the victim is as atypical as the perpetrator is typical, and all of this occurred in an environment (i.e., football locker room) that can be conceptualized as a breeding ground for potential bullying behaviors.

Future Research Implications

One of the conclusions of the Wells Report (Wells et al., 2014) was that bullying is an omnipresent problem that transcends athletic environments across the high school, college, and professional domains. Researchers and clinicians need to recognize that even NFL-caliber 300-pound seemingly superhuman athletes are still people who can be deeply affected by bullying, taunting, and insults. For this and many other reasons, a culture of respect must be promoted and enforced within the professional sport workplace. This includes establishing guidelines,

rules, and consequences for bullying behaviors, just as it is expected in non-sport workplace and personal contexts. The culture of the player-regulated locker room needs to be addressed and incorporated into this process.

Furthermore, a holistic perspective of the athlete as a human being who also happens to be a contact sport participant (e.g., football player) may help to dispel the notion that bullying or violence is more acceptable or even condonable in sport. Beyond this perspective, there are a number of research questions that need to be addressed concerning bullying and violence among male athletes, particularly those who play contact sports.

Mutz (2012) found that different types of sports have differing impacts on pro-social or antisocial outcomes in youth sport participants, in relation to sport involvement and the approval and use of violence. More research regarding this relationship is needed, as the literature in this area is sparse. Although research has found that boys do not have a tendency to act aggressively prior to practicing combat sports (Endresen and Olweus, 2005; Reynes and Lorant, 2001), more research should be conducted to examine whether a predisposition to violence prompts engagement in combat sports, or whether combat sports initiate and foster aggression, leading to violent behavior. Mutz (2012) also suggests that future studies in violence in combat sports should examine the subtle differences among sports disciplines (e.g., karate vs. boxing). Moral climate and moral expectations of coaches are also worth examining in relation to aggressive and violent behaviors and attitudes (e.g., Steinfeldt et al., 2012).

As we have discussed, violence and bullying is commonly associated with contact sports such as football. When the aggressive behavior that is often praised in sport performance transcends the boundaries of the playing field (Gage, 2008), measures must be taken to prevent and address this transfer when it occurs. While Steinfeldt, Foltz, et al. (2011) highlight the importance of teaching football players to compartmentalize their aggression, Stirling (2008) suggests that future research focus on the implementation of violence and abuse prevention initiatives in order to assess their effectiveness. This includes identifying the nature of the problem, clarifying risk and protective factors, designing and testing interventions, conducting clinical trials to evaluate the interventions, and facilitation of implementation on the grand scale (Stirling, 2008). Stirling also calls for the examination of how maltreatments occur, as well as the short-term and long-term effects on the athlete's personal and professional well-being. Specifically, the varying types of maltreatment (e.g., hazing, verbal abuse, physical abuse) should be explored comparatively and longitudinally, and in relation to prevention and intervention initiatives. The maltreatment experiences of athletes should be examined within a broader research perspective (Shannon, 2013; Stirling, 2008). Identifying risk and resiliency factors would also be valuable to the literature in this area, as specifically related to age, race, gender, ethnicity, sexuality, disability, sport type, career stage, period of competitive season, and level of competition (Messner, 1990). Additionally, Stirling (2008) asks that relationships among coaches, parents, and teammates be examined in relation to the athlete's vulnerability to maltreatment. Such relationships have been found to be influential in the endorsement of group norms and the level of moral atmosphere, i.e., whether or not bullying behavior is acceptable on and off the field (Duffy and Nesdale, 2009; Gini, 2008; Ojala and Nesdale, 2004; Steinfeldt et al., 2012).

In the broader context of bullying in schools, Shannon (2013) suggested that the knowledge on bullying behavior in respective social worlds (e.g., extracurricular activities such as sport) would be benefited by interviewing youths regarding their perceptions and experiences of bullying behavior. This could also lead to the development of structural preventative bullying

measures in youth sport, depending on the wealth of support. Concurrently, the perceived systemic and organizational barriers to addressing bullying would add to the literature and clinical implications for prevention. Steinfeldt et al. (2012) suggest that future research is needed to explore bullying dynamics specifically in the sport environment, in order to connect their findings with previous bullying literature. The relationship between bullying and social teasing is also worth investigating. As seen in the Martin case, many players accused him of not having “thick enough skin.” Other players confessed that they didn’t want to defend Martin when he was being bullied because they didn’t want to become the target of the teasing (Wells et al., 2014).

More research is needed to determine what drives bullying behavior and social compliance. Findings have linked having a high status within peer groups to aggression and bullying (Cillessen and Mayeux, 2007; Pokhrel, Sussman, Black and Sun, 2010; Prinstein and Cillessen, 2003). Furthermore, bullying may be a means to maintain this status, which may be why it shows up traditionally high status groups such as football players (Dijkstra, Cillessen, Lindenberg, and Veenstra, 2010; Caravita Di Blasio, and Salmivalli, 2009). This may be one area of exploration for future research. Aligning with this “jock” identity, Miller (2007) suggests that future longitudinal research is needed to examine the relationships between sport-related identity and variables such as masculine norms and goal orientation.

While Miller and Hoffman (2009) reported a correlation between athletic involvement and risk for suicidality, future research should seek to further tease out this relationship, as more empirical support is needed to make such conclusions. In line with the findings of Miller and Hoffman (2009), future research should combine both quantitative and qualitative analyses of sport-related identities, so as to harness their complexities and variation. Overall, there are substantial areas for growth in bullying research, especially as it relates to athletics and specifically to combat sports such as football. Focusing efforts on testing the effectiveness of prevention and intervention strategies, while further clarifying the factors that contribute to bullying, would be valuable in increasing the literature base in this area.

Future Clinical Implications

In addition to the recommendations for future research, it is also important to consider the clinical implications pertaining to the current literature in bullying in sport. Stirling (2008) proposes a model for the implementation of prevention and intervention initiatives aimed at advocacy, policy, education and research. The importance of empirical support for these types of initiatives is stressed throughout the literature. This includes pilot testing of established interventions as well as evaluation of their effectiveness over time.

Mutz (2012) also stresses the importance of concept education and evaluation of implementation programs for bullying prevention within sports contexts. He purports that identification of the specific factors that make these types of programs successful is essential to the development of effective clinical implementation. Particularly, Mutz mentions that coaches should not promote a “win at all costs” mentality, but rather emphasize respect, fairness, discipline, and team spirit both on and off the playing field, as to counter a possible ego-focused goal orientation. Team morals and values are often influential in sport-related identification, behavior, and attitude. Mutz suggests that the education, implementation, and practice of these values are even more important within combat sport contexts, which contain

an emphasis on physical supremacy and should be accompanied by a high level of self-control (Mutz, 2012).

In further reference to the implementation of anti-bullying programs, Shannon (2013) suggests that the development of a clear statement of an organization's commitment to a safe and positive sport environment is the first step to bullying prevention. Furthermore, policies for both prevention and response to bullying incidents should be established from the get-go. Situational factors in which the likelihood for bullying may be increased must be identified within the respected organizational context. Shannon also states that staff should be educated on the topic of bullying, including prevention methods and how to recognize its occurrence. Closing the gap between bullying prevention and intervention in schools vs. sport environments would also be helpful in reducing the occurrence of incidents in either context. This requires communication, organization, and implementation of appropriate procedures in both systems, as well as consistency in terms of expectations, response, and consequences for bullying behavior. Climates that support and encourage positive peer relationships are most beneficial for bullying prevention (Shannon, 2013).

In addition to the organizational aspects of bullying prevention, it is also important to consider the factors at play for the victims themselves. Stafford, Alexander, and Fry (2013) reported that children were unlikely to speak up to adults regarding issues affecting their physical safety and well-being in the sport context. This stresses the need for athletes' input when planning and implementing bullying education, prevention, and intervention programs. Stafford et al. also place responsibility with the coaches for creating and modeling an atmosphere of positive behavior. We currently live in a society which commonly practices and condones aggressive verbal and/or physical coaching methods; this plays a role in the prevalence and permission of violence and aggression among players. It is worth examining the coaches' attitudes and behaviors toward these types of behaviors in depth, in order to determine how much their influence contributes to bullying incidents. It is likely that a coach may be the most influential male in a young [male] athlete's life, a role which has been shown to be the strongest predictor of immoral attitude and behavior (Steinfeldt et al., 2012).

The environmental, social, and cultural factors surrounding bullying behavior should also be taken into consideration for clinical application. Messner (1990) suggested that poor, ethnic minority males are most likely to be disproportionately directed into sports careers due to poverty, institutionalized racism, and scarcity of other career options. Messner stated that due to these issues, athletes with these types of demographic characteristics are more likely to place a higher value on their athletic identity, whereas privileged white males participate in sport primarily for status and are less likely to persist to high-level competition. While this relationship may have shifted in the past two and a half decades, the role of socio, cultural, and economic factors in sport transcends various issues and should be examined in relation to bullying as well. A multicultural approach should be considered for future clinical prevention and intervention of bullying in sport.

Chapter 54

CYBERBULLYING: BULLYING GONE DIGITAL

ABSTRACT

Youths in the 21st century are raised in a digital world where blogs, social networking sites, and instant messaging are part of their everyday life. These youths have been immersed in a digital world for as long as they can remember. As a result of this immersion, youths are at risk for cyberbullying, which has increased in intensity over the years.

Cyberbullying has become a major focus of not only youths, educators, and researchers, but also among the general population, due to high profile cases of cyberbullying victimization involving suicide. This chapter drew on literature utilizing cross-sectional, longitudinal, qualitative, and quantitative research methodologies to describe cyberbullying.

The chapter provided an overview of cyberbullying, including the tools, technologies, and forms, along with the prevalence rates, correlates, and the emotional and behavioral consequences. *Also discussed are the cultural differences in these behaviors, and theoretical underpinnings.* The chapter concluded with recommendations for future research and public policy.

CYBERBULLYING: BULLYING GONE DIGITAL

Millions of children and adolescents utilize electronic technologies (e.g., cell phones, the Internet) everyday, engaging in many different behaviors (Madden, Lenhart, Duggan, Cortesi, and Gasser, 2013). Although their usage of such technologies has many benefits (e.g., fast communication with friends and family, access to an array of rich information), there is also a darker side to youths' electronic interactions: Cyberbullying. An extension of traditional bullying, cyberbullying is a form of bullying which takes place by means of electronic technologies, such as email, instant messaging, Facebook, and text messaging through mobile devices (Cost, 2012; Olweus, 1999). Due to the ability to remain anonymous, the cyber context offers flexibility to cyberbullies, allowing them to harm their potential victims without the constraints and many of the repercussions associated with traditional face-to-face bullying. Cyberbullies can also target the victim or victims quicker, more often, and involve multiple bystanders in the bullying situation. For example, an embarrassing video of a victim or victims can be shared quickly by sending it to multiple recipients, who can also share the video as well.

Drawing on research from a variety of disciplines, such as psychology, education, social work, sociology, and computer science, this chapter is organized into nine sections. These sections include:

- A review of case studies involving cyberbullying victimization is given in the first section.
- Definitions, technologies used, the role of anonymity, and prevalence rates of cyberbullying are described in the second section.
- In the third section, the characteristics and risk factors associated with cyberbullying involvement are discussed.
- The fourth section detailed the relationship between parents and cyberbullying involvement.
- In this section, the roles of peers and school in youths' cyberbullying involvement are explained.
- The sixth section reviews research findings on the psychological and behavioral consequences resulting from cyberbullying involvement.
- Cross-cultural differences in cyberbullying are discussed in the seventh section.
- In the eighth section, two theories, social cognitive theory and online disinhibition effect, are applied to cyberbullying.
- Concluding the chapter is a discussion of future research and public policy recommendations.

CASE STUDIES OF CYBERBULLYING VICTIMIZATION

At 6 p.m., October 10, 2012, fifteen-year-old Amanda Todd hung herself in her Port Coquitlam, British Columbia, Canada home only five weeks after she posted a gripping video on YouTube which detailed how she was harassed and bullied online for years. The video she posted was entitled, "My Story: Struggling, bullying, suicide and self harm." The video described Amanda's story on a series of flash cards. While she was in 7th Grade, Amanda had

an online video conversation with an unknown person. In the course of their conversation, Amanda was asked to flash her naked breasts, which she did. A year later, she was contacted by the person who threatened to post her pictures on the Internet if she didn't provide more naked content. She refused and subsequently had her pictures posted to family and friends alike. She became depressed and anxious, turning to alcohol and drugs in order to cope with this situation. Despite switching schools, the cyberbullying followed her. A Facebook page of her with the picture of her breasts as the profile picture was created. Her schoolmates began to make fun of her, calling her names. She started cutting herself. She moved to yet another school. She made friends but unknowingly began dating a boy who already had a girlfriend. The girlfriend attacked her; the incident was filmed and posted online. Despondent, Amanda tried to kill herself by drinking bleach. She was rushed to the hospital and survived but in the end, the abuse was too much, so she hung herself (Pendergrass and Wright, in press).

On December 9, 2012, sixteen year old Fivay High School student from Hudson, Florida, Jessica Laney, hung herself. Her friends told the authorities that she became suicidal after being cyberbullied and abused through the anonymous Latvian question and answer website "Ask.fm." While Laney's Ask.fm account page, Jessicamarieeee1, had its fair share of innocent and friendly comments, there were also a number of posts telling her how fat she was and what a loser she was.

Classmates of 16-year-old Jessica Laney say she was pretty and bubbly. Still, cruel comments could be found on her Ask.fm webpage. "Nobody even cares about you," reads one anonymous post. "Can you just kill yourself," says another. Close friends Cheyenne Ellsmore and Lisa Arthur say people would post the mean messages anonymously. "You get compliments sometimes but it's those negative comments that bring you down," Ellsmore said. "There's just things you should say and things you shouldn't," said Arthur. "And on Ask.fm, none of that should be said." The girls believe the comments got to be too much for Laney, who took her own life Sunday night. (McVey, 2012)

Rehtaeh Parsons, a seventeen-year-old Cole Harbour District High School student, attempted suicide by hanging on April 4, 2013, in her home in Dartmouth, Nova Scotia, Canada. She did not succeed which led to a coma and brain death. Three days later her family made the decision to take her off life support; she died that day. Back in November of 2011, Rehtaeh was at a small gathering of friends when she was unbeknownst photographed while having sex with (her mother called it rape) one of the boys. After that, the bullying and harassment began unabated. Her mother, Leah Parsons said, "She was never left alone. She had to leave the community. Her friends turned against her. People harassed her. Boys she didn't know started texting her and Facebooking her asking her to have sex with them. It just never stopped" (The Huffington Post, 2013). The family moved to nearby Halifax but the cyberbullying did not stop. Rehtaeh began to suffer from depression and anger, and at one time had to be admitted to a hospital on fears that she would harm herself. After her death, a year-long investigation by the Royal Canadian Mounted Police concluded that there was not enough evidence to charge and convict any of the boys with rape (Pendergrass and Wright, in press).

On September 9, 2013, Rebecca Ann Sedwick, a twelve year old Crystal Lake Middle School student, leaped to her death at a cement factory less than a mile from her home in Lakeland, Florida. She had been the victim of cyberbullying for months. Rebecca had been reported missing about 7 p.m. Monday by her mother after she failed to return home from school that day. After an investigation, two girls were arrested, part of a group of 15 girls who

were accused of tormenting Rebecca until she took her own life. The arrests came after one of the two girls tweeted “Yes IK [I know] I bullied REBECCA nd [sic] she killed her self [sic] but IDGAF [I don't give a fuck]” (Quigley and Gorman, 2013). The torment began after one of the girls began dating a boy whom Rebecca had dated earlier. She eventually turned the other girl, formerly a good friend of Rebecca’s, against Rebecca.

Witnesses told investigators she sent messages to Rebecca, calling her ugly, telling her to “drink bleach and die,” and encouraging her to kill herself. Rebecca's computer searches revealed she had searched for ways to commit suicide and asked questions like, “What is overweight for a 13-year-old girl?” One of the Florida girl's screensavers also showed Rebecca with her head resting on a railroad track. Rebecca changed one of her online screen names to “That Dead Girl.” Later, she messaged a boy: “I'm jumping.” Polk County Sheriff Judd said Rebecca had been “absolutely terrorized” by the other girls. “We can see from what we've been investigating so far that Rebecca wasn't attacking back,” Judd said. “She appeared to be beat down. She appeared to have a defeatist attitude. And quite frankly, the entire investigation is exceptionally disturbing”. (Quigley et al., 2013)

Even when Rebecca’s mother transferred her to another school, the bullying continued online. In December of 2012, Rebecca was hospitalized for three days after cutting her wrists, noting that it was because of bullying.

“She put on a perfect, happy face. She never told me,” said her mother, Tricia Norman. “I never had a clue. I mean, she told me last year when she was being bullied, but not this year, and I have no idea why.” Once police checked [Rebecca’s] cell phone they discovered that the bullying had not stopped, especially on Kik Messenger, Instagram and Ask.fm. “They would tell her she's ugly, stupid, nobody liked her, go kill herself,” Ms. Norman said. (Quigley et al., 2013)

All these recent cases of cyberbullying which led to suicide raise the questions: what actually is cyberbullying, how do we define it, how do we recognize it, how do we protect against it and how do we educate those who we count on to protect youths? With the exponential prevalence of personal contact and communication devices in society nowadays, we cannot afford to ignore the danger of an increasingly interconnected and interdependent societal shift from the days of the schoolyard bully to the now ever-prevalent and unshakable cyberbully. Youth deserve to be protected, parents and teachers deserve to understand the threat, and our society needs to embrace the fact that electronic communication has become important to youths’ lives, if not more important, than personal interactions.

WHAT IS CYBERBULLYING?

Defined as youths’ usage of modern technologies to deliberately embarrass or intimate others in a repetitive and hostile manner, cyberbullying, like traditional face-to-face bullying, is also characterized by an imbalance of power between the bully and the victim (Ferdon and Hertz, 2007; Kowalski and Limber, 2007; Topcu, Erdur-Backer, and Aydin, 2008; Wolak, Mitchell, and Finkelhor, 2007; Ybarra, West, and Leaf, 2007). As deliberate behaviors, cyberbullying behaviors are intentionally carried out by perpetrators with malicious intent (Grigg, 2010). When cyberbullying involves repetition, it can mean that the perpetrator targets

the victim multiple times and that the humiliating video or nasty text message can be viewed and shared by various bystanders (Vandebosch and Van Cleemput, 2008). As an extension of the traditional face-to-face bullying definition (Olweus, 1999), the definition of cyberbullying adds a technological component. In traditional face-to-face bullying, a bully might punch, kick, or spread a rumor about the victim. Separate from this type of bullying, cyberbullying involves a bully sending unkind text messages and emails, sharing secrets about the victim by posting or sending the secret to someone else, or uploading an embarrassing picture or video of the victim with malicious intent.

There are various examples of cyberbullying behaviors. Some behaviors include making anonymous phone calls, sending abusive emails, theft of identity information or pretending to be someone else, and harassment via instant messenger, social networking sites, and text messages (Wolak et al., 2007; Wright and Li, 2012; Ybarra and Mitchell, 2004). Other cyberbullying behaviors are similar to face-to-face bullying behaviors but they are carried out in the cyber context, including harassment, insults, physical threats, social exclusion, and humiliation (Chisholm, 2006). Extending these behaviors, Rideout and colleagues (2005) also described cyberbullying as encompassing the distribution of explicit videos via various websites, such as social networking sites and online gaming sites. Other forms of cyberbullying behaviors include happy slapping and flaming (Gillepsi, 2006; Smith et al., 2008). In recent research, Arslan et al. (2012) found that the most frequently used technologies to harm others were instant messaging tools and social networking sites (e.g., Facebook, Twitter), which were reported by over half of their sample.

To understand why youths might engage in cyberbullying, some researchers have explained that new technologies allow bullies to hide their identities, which could exacerbate the power differential between the bully and the victim (Wright, 2013; Ybarra et al., 2007). Furthermore, these new technologies allow the bully to engage in repeated and prolonged harassment, while remaining anonymous (Maher, 2004; Wolak et al., 2007; Wright, 2014a; Ybarra and Mitchell, 2004). Therefore, it is not surprising that many youths who engage in cyberbullying choose to remain anonymous while executing their attack (Dehue, Bolman, and Vollink, 2008; Kowalski and Limber, 2007; Wright, 2014a; Ybarra and Mitchell, 2004). The proposal that anonymity is a motivator for cyberbullying is corroborated by research indicating that many cyberbullying victims are often unsure of the identity of the cyberbully (Kowalski and Limber, 2007; Ybarra et al., 2007). The majority of victims, around 80%, in one study were unaware of the identity of the cyberbully (Arslan et al., 2012). The ability to remain anonymous in the cyber context represents an imbalance of power between the victim and the anonymous perpetrator (Vandebosch and Van Cleemput, 2008; Grigg, 2012). Research (e.g., Moore, Nakano, Enomoto, and Suda, 2012) demonstrates that the ability to post anonymously in forums triggers more cyberbullying attacks than less anonymous forums. In recent research, Wright (2013; 2014a) found that feeling more confident with one's ability to remain anonymous in the cyber context was related positively to cyberbullying, especially cyberbullying perpetrated anonymously. Not only is anonymity an issue because it might drive youths toward cyberbullying, but it also intensifies victims' negative feelings, leading to powerlessness (Dooley, Pyzalski, and Cross, 2009; Nocentini, Galmaestra, and Schultze-Krumbholz, 2010; Slonje and Smith, 2008; Vandebosch and Cleemput, 2008; Smith et al., 2008).

Despite the differences in the prevalence rates of cyberbullying, generally due to variations in samples and measurement techniques, understanding how frequently youths are involved in

these behaviors is helpful for prevention efforts. One of the earliest studies of cyberbullying in the United States reported that 50% of youths in their sample experienced these behaviors as victims (Wolak et al., 2007). Other studies have found lower rates of cyberbullying involvement in the United States. For example, using a sample of 3,767 middle school students (aged 11-14), Kowalski and Limber (2007) found that 11% had been cyberbullied, 4% had bullied other youths, and 7% were cyberbullies and cyber-victims. Similar estimates concerning the perpetration of cyberbullying were found by Patchin and Hinduja (2006). They found that 29% of their sample reported cyber victimization and that 47% had witnessed cyberbullying. Among youths in Hawaii (N = 677, grades 9-12th), 56.1% reported that they were the victims of cyberbullying (Goebert, Else, Matsu, Chung-Do, and Chang, 2011). In more recent research in the United States, Hinduja and Patchin (2013) found that 4.9% of youths in their sample (N = 4,441, 6-12th grade) had cyberbullied someone in the past 30 days. Utilizing a sample of 1,972 Canadian youths (10th graders), Cappadocia et al. (2013) reported that 2.1% of youths were cyberbullying perpetrators, 1.9% were cyber-victims, and 0.6% were both cyberbullies and cyber-victims. Rates of cyberbullying perpetration and victimization were slightly higher among 399 Canadian youths (grades 8-10th), with 6% reporting that they were perpetrators, 5.8% as victims only, and 5% as cyberbullies and cyber-victims (Bonanno and Hymel, 2013).

Cyberbullying is not a phenomenon linked to only one country, but instead a global concern. Therefore, researchers have directed their attention to cyberbullying involvement in countries, other than the United States and Canada. Drawing on a large Swedish sample (N = 22,544, ages 15-18), Laftman, Modin, and Ostberg, (2013) reported that 5% of their sample were victims of cyberbullying, 4% were perpetrators, and 2% were both cyberbullies and cyber-victims. In a younger sample of 7th through 9th grade Swedish youths, 1.9% were cyber-victims, 2.9% were cyberbullies, and 0.6% were cyberbullies and cyber-victims (Beckman, Hagquist, and Hellstrom, 2012). Similar rates of cyber victimization (6% for Ireland, 6.3% for Belgian, and 4.5% for Australia) were found among Irish (N = 876, ages 12-17; Corcoran, Connolly, and O'Moore, 2012), Belgian (N = 1,042, M age = 15.47; Heirman and Walrave, 2012), and Australian (N = 3,112, grades 6-12th; Campbell, Spears, Slee, Butler, and Kift, 2012) youths. However, rates of cyber victimization were higher (12.5%) among Italian youths (N = 2,326, M age = 13.9 years; Brighi, Guarini, Melotti, Galli, and Genta, 2012). Among German youths (N = 276, ages 13-19 years), 13% were classified as cyberbullies and 11% as cyber-victims (Festl, Scharkow, and Quandt, 2013). In Turkey, estimates of cyberbullying victimization vary from 18% (N= 756, 7th graders; Yilmaz, 2011) to 32% (N= 276, ages 14-18; Erdur-Baker 2010). The rates of being a perpetrator of cyberbullying are 6% (Yilmaz, 2011) to 19% (ages 12-14 year olds; Ayas and Horzum, 2012) among youths in Turkey. In another study, Aricak and colleagues (2008) found that 36% of their sample (N = 269, Turkish secondary school students) were cyberbullies. Although higher than cyber victimization rates from some European countries, but not as high as those in Turkey, Olenik-Shemesh and colleagues (2012) found that 16.5% of their Israeli participants (N = 242, 13-16 years old) were victims of cyberbullying. Lazuras et al. (2013) investigated rates of cyberbullying involvement as witnesses or victims of cyberbullying. Their findings revealed that 32.4% of the sample (N = 355, 13-17 years old) were involved in cyberbullying as victims or bystanders. Cyber victimization (24.9%) rates were comparable among Spanish youths (N = 845, M age = 15.2 years; Gamez-Guadiz, Orue, Smith, and Calvete, 2013).

Research on cyberbullying perpetration and victimization has been slower to develop in Asia. Among Taiwanese (N = 545) youths, 63.4% witnessed cyberbullying, 34.9% were cyberbullied, and 20.4% had cyberbullied others (Huang and Chou, 2010). In Korea, 43% of youths in one sample (N = 3,238, 8th graders) reported that they were involved in cyberbullying either as victims or perpetrators (Jang, Song, and Kim, 2014). Rates of cyberbullying perpetration and victimization were similar in China, with 34.8% of youths admitting that they had cyberbullied someone and 56.9% indicating that they were cyberbullied (N = 1,438 high school students; Zhou, Tang, Tian, Wei, Zhang, and Morrison, 2013). Another study focused on cyberbullying through Facebook among 1,676 13-17 year olds in Singapore (Kwan and Skoric, 2013). Of these youths, 59.4% reported that they experienced victimization through Facebook and 56.9% perpetrated Facebook cyberbullying. In a recent study, Wong and colleagues (2014) found that 13.1% of youths in their sample (N = 1,912, 12-15 year olds) reported cyberbullying perpetration and 12.2% indicated cyber victimization. Considering rates of cyberbullying around the world, there is further need to continue investigating cyberbullying among youths, and understanding risk factors associated with the involvement in these behaviors.

CHARACTERISTICS OF CYBERBULLIES AND CYBER-VICTIMS

Researchers have focused their attention on the risk factors associated with youths' involvement in cyberbullying as perpetrators, victims, and bully-victims. Demographic variables represent the first cluster of risk factors examined in this research. One highly researched risk factor is age. In this research, younger youths were at a greater risk of being cyberbullied, whereas older youths were most frequently the perpetrators of cyberbullying (Ayas and Horzum, 2012). In addition, Williams and Guerra (2007) found that physical forms of bullying and cyberbullying peaked in middle school, but declined in high school. However, age is not a consistent predictor of cyberbullying involvement as Wade and Beran (2011) found that being in the 9th grade increased the risk of cyber victimization and cyberbullying perpetration in comparison to when the youths were in middle school. Like age, gender is also an inconsistent predictor of cyberbullying involvement. Some researchers (Li, 2007; Ybarra et al., 2007) have found that boys were more often the perpetrators of cyberbullying in comparison to girls and that girls experienced cyber victimization more frequently than boys (Hinduja and Patchin, 2007; Kowalski and Limber, 2007). On the other hand, other research has indicated that girls engaged in more cyberbullying perpetration when compared to boys (e.g., Dehue et al., 2008; Pornari and Wood, 2010) and that boys reported higher rates of cyber victimization than girls (e.g., Akbulut, Sahih, and Eristi, 2010; Erdur-Baker, 2010; Huang and Chou, 2010). Yet, other researchers have found no gender differences in cyberbullying involvement (Beran and Li, 2005; Wright and Li, 2013b).

Other frequently researched risk factors include both traditional face-to-face bullying and victimization. Various research studies find significant positive relationships between cyberbullying and traditional face-to-face bullying as well as associations between cyber victimization and victimization by face-to-face bullying (Cappadocia et al., 2013; Mitchell et al., 2007; Steffgen, Kong, Pfetsch, and Melzer, 2011; Fanti, Demetriou, and Hawa, 2012). Face-to-face bullying victimization is also a risk factor for victims and perpetrators of cyberbullying

(Wright and Li, 2012). Another risk factor associated with cyberbullying includes frequent Internet use. In particular, higher rates of Internet usage are associated positively with both cyberbullying perpetration and victimization (Arıcak et al., 2008; Ybarra and Mitchell, 2004). Cyber-victims report higher rates of chatting, emailing, blogging, gaming, and sending instant messages when compared to non-victims (Smith et al., 2008; Ybarra and Mitchell, 2004). A potential explanation for the relationship between Internet usage and cyberbullying involvement is that the disclosure of personal information worsens online risks, like cyberbullying (Ybarra et al., 2007). Therefore, frequent Internet usage might increase youths' willingness to disclosure personal information online, marking them more vulnerable to victimization. There is research evidence that psychosocial adjustment difficulties are also cyberbullying risk factors. Internalizing problems, such as depressive symptoms, place youths at risk for cyber victimization as such problems might make victims more vulnerable to attacks (Cappadocia et al., 2013; Mitchell et al., 2007; Ybarra and Mitchell, 2004). Externalizing problems, like alcohol use, are related positively to cyberbullying perpetration (Cappadocia et al., 2013). In addition, higher normative beliefs about face-to-face bullying and cyberbullying are linked to cyberbullying perpetration (Ang, Tan, and Mansor, 2010; Burton, Florell, and Wygant, 2013; Wright and Li, 2013a), indicating that cyberbullies view bullying behaviors as normative. Also, lower levels of provictim attitudes (i.e., children's beliefs that bullying is unacceptable, and defending victims is valued) were related to greater cyberbullying (Elledge, Williford, Boulton, DePaolis, Little, and Salmivalli, 2013). Research also indicates that low self-control (Jang et al., 2014), less empathy (Steffgen et al., 2011), and moral disengagement (Lazuras et al., 2013; Robson and Witenberg, 2013) were associated with cyberbullying perpetration. In one study aimed at understanding the longitudinal risk factors associated with cyberbullying involvement, Fanti et al. (2012) found that media violence exposure, and callous and unemotional traits assessed predicted cyberbullying perpetration one year later. However, media violence exposure was the only risk factor associated with cyber victimization. Recent research has also indicated that perceived stress from parents, peers, and academics increases cyberbullying perpetration one year later (Wright, in press). Thus, there are a variety of individual characteristics that make youths vulnerable to cyberbullying involvement. Similarly, youths' relationships with their parents have also been found to be risk factors as well.

PARENTS' ROLES IN THEIR CHILDREN'S CYBERBULLYING INVOLVEMENT

Ample research literature links traditional face-to-face bullying with parental monitoring. In this literature, parents with permissive parenting styles are less likely to acknowledge their children's activities (Marini, Dane, Bosacki, and Ylc-Cura, 2006). Parents of bully-victims frequently utilize an indifferent-uninvolved parenting style, and inconsistently monitor their children's activities (Duncan, 2004). Such findings are important as high levels of parental monitoring are correlated negatively with bullying behaviors (Totura et al., 2009). On the other hand, enmeshed and overprotective family backgrounds are typically associated with victims of bullying (Smith, Madsen, and Moody, 1999). It is hypothesized that such families do not allow their children to develop assertiveness and practice necessary skills for social interactions. The cyber context presents another environment in which parents might decide to

monitor their children's activities. In one study, Mason (2008) found that 30% of youths used the Internet for three hours or more daily and that, during the time that they were online, less than 50% reported parental monitoring. In other research, Aoyama and colleagues (2011) revealed that parental mediation and monitoring of their children's online activities were not effective because some parents lack technological skills and many fail to follow-up on the strategies they implemented. Furthermore, many parents report that they are unsure of what their children are up to online and that they are uncertain of how to even discuss the topic of online activities with their children (Rosen, 2007). Rosen also found that many parents set limits on their children's Internet consumption, but many do not actually monitor these limits. Although 93% of parents in one study reported that they set limits on their children's online activities, only 37% of their children reported being given rules from their parents about such activities (McQuade et al., 2009).

Other research has focused on the relationship between family characteristics (e.g., household factors, parenting styles, parental monitoring) and cyberbullying involvement. Findings indicated that poor caregiver monitoring and poor emotional bonds with caregivers were related positively to cyberbullying (Ybarra and Mitchell, 2004). There is no evidence that family income, parental education, and caregiver status (single or married) were associated with cyberbullying perpetration or cyber victimization. However, research does indicate that parental unemployment increases the risk of youths' involvement in cyberbullying as perpetrators and victims (Arslan et al., 2012). Youths with neglectful parents are at greater risk for engaging in and experiencing cyberbullying when compared to non-involved youths (Dehue, Bolman, Vollink, and Pouwelse, 2012). In addition, authoritarian parenting styles were related positively to cyber victimization. The risk of cyber victimization is also increased when parents do not monitor or set rules pertaining to the types of websites their children are allowed to visit (Mesch, 2009; Navarro, Serna, Martinez, and Ruiz-Oliva, 2013). Other research (i.e., Hinduja and Patchin, 2013) suggests that youths who believed that their parents or other adults would punish them for participating in cyberbullying were less likely to engage in such behaviors. These findings indicate the importance of parents' involvement in their youths' online activities.

PEERS AND SCHOOLS CONTRIBUTIONS TO CYBERBULLYING

Youths spend most of their time in school until they graduate from high school or college (Parker, Rubin, Erath, Wojslawowicz, and Buskirk, 2005). Therefore, it is not surprising that many studies have revealed that youths' involvement in bullying behaviors is connected to their peers and school environment. In this literature, teachers' perceptions and awareness of cyberbullying vary greatly (Kochenderfer-Ladd and Pelletier, 2008). Cyberbullying presents a complicated consideration for teachers as many educators perceive overt forms of bullying more harshly than they do covert forms, like relational aggression and some forms of cyberbullying (Sahin, 2010). The relationship between cyberbullying and the school is further complicated because many cyberbullying incidences occur off school grounds through electronic technologies, making it difficult for teachers to even be aware of such incidences (Mason, 2008). In addition, many teachers are not trained to properly deal with and recognize such behaviors. Corroborating this proposal, Cassidy and colleagues (2012a) found that some Canadian teachers were unfamiliar with newer technologies, making it difficult for them to deal

effectively with cyberbullying. Other research also indicates that Australian teachers were more likely to focus on face-to-face bullying prevention than cyberbullying prevention (Tangen and Campbell, 2010). When teachers were concerned about cyberbullying, this concern rarely translated into policy or programs (Cassidy, Brown, and Jackson, 2012b). Educators must recognize the importance of addressing cyberbullying as the consequences of cyberbullying are felt at school as it impacts the learning process (Shariff and Hoff, 2007). In particular, youths involved in cyberbullying as victims or perpetrators perceived school and teachers less positively than non-involved youths (Bayar and Ucanok, 2012). The fearfulness of classmates who might be perpetrators of cyberbullying can divert youths' attention from academic tasks, reducing learning opportunities (Eden, Heiman, and Olenik-Shemesh, 2013). Furthermore, lower school commitment (Ybarra and Mitchell, 2004) and a negative school climate (Williams and Guerra, 2007) increase cyberbullying perpetration. The literature does indicate the importance of educators for addressing cyberbullying through awareness and prevention. Teachers with confidence in their abilities and a strong commitment to their school are more likely to learn about cyberbullying, boosting their awareness and abilities to effectively manage these behaviors (Eden et al., 2013). However, teachers' motivations for learning about cyberbullying and believing that they can manage cyberbullying decreases from elementary school to middle school. Such results represent a substantial problem as cyberbullying usually increases in the middle school years (Ybarra et al., 2007) and that teachers' ability to intervene at the classroom level is a protective factor associated with cyberbullying (Elledge et al., 2013).

Peers exert a strong influence on youths' behaviors and social norms concerning acceptable and unacceptable behaviors (Miller and Prentice, 1996). Support for such influences was found by Festl and colleagues (2013). In particular, their results revealed that the best predictor of cyberbullying perpetration and victimization were classes with higher rates of cyberbullying incidences. Similarly, youths who believed that their friends engaged in cyberbullying were more likely to perpetrate cyberbullying themselves (Hinduja and Patchin, 2013). Rather than focusing on how peers influence youths' cyberbullying perpetration, other research aims to understand the nature of youths' relationships with their peers. In this research, peer attachment was associated negatively with cyberbullying perpetration and cyber victimization (Burton et al., 2013). Like victimization by face-to-face bullying, cyber victimization is associated with peer rejection after controlling for face-to-face victimization (Wright and Li, 2013b). There is also research evidence which indicates that cyberbullying might be utilized to boost youths' status among their peers. In this research, Wright (2014b) found that higher levels of perceived popularity, a reputational type of popularity in the peer group, increased youths' cyberbullying perpetration six months later.

PSYCHOLOGICAL AND BEHAVIORAL CONSEQUENCES

Various research studies have been conducted on the psychological and behavioral consequences associated with cyberbullying involvement. In this research, cyber-victims reported lower global happiness (i.e., how generally happy they were), school happiness, school satisfaction, family satisfaction, and self-satisfaction (Navarro et al., 2013). In addition, cyber-victims generally felt more anger (Dehue et al., 2008), fear (Beran and Li, 2005), and sadness (Patchin and Hinduja, 2006) when compared to non-involved youths. Cyber-victims also report more emotional and peer problems when compared to cyberbullies. Cyberbullying involvement

is also linked to academic difficulties. Results from this research indicated that cyberbullies and cyber-victims both experience problems in school, such as decreased motivation for school, lower academic attainment, and increased school absences (Beale and Hall, 2007; Beran and Li, 2007). Cyberbullies and cyber-victims also report internalizing (e.g., depression, anxiety) and externalizing problems, such as the engagement in aggressive behaviors and the usage of drugs, and alcohol (Arslan et al., 2012; Li, 2007; Patchin and Hinduja, 2012; Wright, in press; Ybarra et al., 2007). Hinduja and Patchin (2010) proposed that victims of cyberbullying might be at an increased risk of suicide when compared to cyberbullying perpetrators and victims of traditional bullying. Finding partial support for this proposal, Bauman and colleagues (2013) found that perpetrating and experiencing cyberbullying were both related to suicide attempts. However, traditional face-to-face bullying and victimization were stronger predictors of suicidal thoughts, plans, and attempts than cyber victimization, but not cyberbullying perpetration. Although Bauman et al. explain that their results concerning cyberbullies might be a joke perpetrated by their participants, their findings are consistent with Beckman and colleagues (2012) who found that cyberbullies were just as likely as cyber-victims to be at risk for mental health problems. Further supporting the association between cyberbullying perpetration and mental health issues, research (Sourander et al., 2010) results indicated that psychiatric and psychosomatic problems were also associated with cyberbullying involvement.

Other research has focused on the joint effects of traditional bullying and cyberbullying on youths' psychological and behavioral outcomes. In this research, victims of both traditional face-to-face bullying and cyberbullying reported more internalizing problems when compared to youths who experienced only one type of victimization (Gradinger, Strohmeier, and Spiel, 2009; Perren, Dooley, Shaw, and Cross, 2010). Much of the research focused on the psychological and behavioral consequences associated with cyberbullying involvement do not account for traditional face-to-face bullying and victimization. Such considerations are important as there are considerable associations among cyberbullying and face-to-face bullying involvement (Williams and Guerra, 2007; Wright and Li, 2013b). Research indicates that cyberbullying perpetration and cyber victimization are both related to depressive symptoms and suicidal ideation after including face-to-face bullying and victimization in the same model (Bonanno et al., 2013). Utilizing a similar design, Brighi and colleagues (2012) found no support for an association between cyber victimization and loneliness or self-esteem.

CROSS-CULTURAL RESEARCH ON CYBERBULLYING

Considering that there is increasing evidence that cyberbullying is a global phenomenon, more attention has been given to cross-cultural investigations of youths' involvement in these behaviors. Much of the research focused on cross-cultural differences in cyberbullying perpetration and victimization classify countries according to an independent self-construal (i.e., viewing the self as separate from the social context and emphasizing autonomy) or an interdependent self-construal (i.e., viewing themselves within the broader social context; Singelis, 1994). Generally, people from Western countries, like the United States, Canada, and England, are primed and reinforced for behaving according to an independent self-construal, whereas people from Eastern countries, such as China, Korea, and Japan, are primed and reinforced for behaving consistently with an interdependent self-construal. The available research indicates that such differences in self-construal affect a variety of social behaviors,

including bullying. Independent and interdependent self-construals have been applied to explain cyberbullying behaviors. In one study, Barlett and colleagues (2014) found that participants from the United States self-reported greater levels of cyberbullying than Japanese participants, and that these relationships were moderated by positive attitudes toward cyberbullying. In particular, such associations were stronger among U.S. participants when compared to Japanese participants. Aoyama and colleagues (2011) also found that Japanese high school students reported less cyberbullying than U.S. high school students. Japanese youths also engaged in less cyberbullying behaviors in comparison to Austrian youths (Strohmeier, Aoyama, Gradinger, and Toda, 2013). Similar patterns were found among Chinese and Canadian youths (Li, 2008). Canadian youths self-reported more cyberbullying and knew someone who had been cyberbullied more often than Chinese youths. There were no cultural differences found concerning cyber victimization. However, in another sample, Li (2006) found that Chinese youths were more likely to be cyber-victims when compared to Canadian youths. Further delineating cyberbullying according to the proactive (to obtain a goal) and reactive (response to provocation) classifications, Shapka and Law (2013) found that East Asian youths from Canada engaged in cyberbullying for proactive reasons, whereas Canadian youths did so for reactive reasons. Cross-cultural gender differences in cyberbullying have also been found. In particular, Italian males engaged in more cyberbullying when compared to Spanish and English males (Genta et al., 2012). Additional research is still needed to understand differences in cyberbullying involvement across the world, especially in South America, Africa, and India.

THEORETICAL UNDERPINNINGS

In this section, two theories, the social cognitive theory and the online disinhibition effect, will be discussed, along with their applications to cyberbullying. Within the social cognitive theory framework, researchers propose that adolescents model the behaviors of their parents and/or friends (Duncan, 2004; Hinduja and Patchin, 2008; Mouttapa, Valente, Gallaher, Rohrbach, and Unger, 2004). Olweus (1993) applied the social cognitive theory to explain youths' aggressive behaviors. In his explanation, Olweus proposed that the effects of the model are stronger when the observer has a positive evaluation of the model, such as perceiving the model as tough or fearless. Perceiving the model's aggressive behaviors as positive makes these acts less inhibited for the observer, especially if the model is rewarded for the aggressive actions. Usually the reward involves the bullies' victory over the victim. Barlett and Gentile (2012) elaborated on the social cognitive theory by applying this theory to youths' involvement in cyberbullying. Through observations of successful cyberbullying incidences, many youths learn that cyberbullying is an appropriate aggressive action. The unique features of the cyber context also aid in the social learning behind cyberbullying. That is, cyberbullies learn that they might experience little or no immediate consequences for their behaviors and that they can further increase their ability to not get caught engaging in cyberbullying if they remain anonymous, which they are better able to do in the cyber context (Vandebosch and Van Cleemput, 2008). There is research evidence that being positively reinforced for cyberbullying contributes to youths' positive attitudes toward these behaviors (Barlett and Gentile, 2012). Such positive attitudes relate to later engagement in cyberbullying (Wright and Li, 2013a).

Distinct from the social cognitive theory, which focuses on successful cyberbullying shaping positive attitudes toward these behaviors, the online disinhibition effect proposes that people in cyberspace might not behave in similar ways as they would in real life (Suler, 2004). A core tenant to this theory is that the online environment allows people to loosen or abandon their typical social restrictions and inhibitions that are present in normal face-to-face interactions (Mason, 2008). There is a variety of research demonstrating that people do behave more bluntly when communicating via various electronic technologies. In this early research, McKenna and Bargh (2000) found that there were more misunderstandings, greater hostility, and aggressive behaviors in computer-mediated communication when compared to face-to-face communication. The online environment also removes the ability to see emotional reactions, which might prevent people from modulating their own behavior as they are not able to witness the consequences of their actions (Kowalski et al., 2008). When it comes to cyberbullying, the cyberbully may not witness cyber-victims' reactions, or experience social disapproval and punishment (Willard, 2007). Over time, cyberbullies' behaviors might become more disinhibited, especially when they receive positive reinforcement, fail to recognize the consequences of their behaviors, and lose control of the typical inhibitions present in face-to-face interactions (Hinduja and Patchin, 2009; Wright, 2014a). Another core component of the online disinhibition effect is deindividuation (Joinson, 1998). Deindividuation occurs when people are not accountable for their actions, and anonymity might further reduce accountability. Anonymity in the cyber context, along with the online disinhibition effect, allows youths to distinguish their actions from the real world and their identity, making it easier for them to harm others electronically (Wright, 2014a).

RECOMMENDATIONS

Based on the extensive research reviewed in this chapter, there are a few noticeable gaps in the literature which should be addressed by future research. One recommendation is for research to follow-up investigating the concept of anonymity as applied to cyberbullying. Youths can also engage in anonymous traditional face-to-face bullying, such as anonymously slipping a nasty note in a peer's locker. Therefore, future research should aim to understand more about the differences in youths' conceptualizations of anonymous acts both online and offline, and which factors might contribute to their decision to choose anonymous cyberbullying versus anonymous traditional face-to-face bullying. Similarly, this research should also examine the differences in non-anonymous cyberbullying versus anonymous cyberbullying through social applications, like Ask.fm, or Yik Yak. There is also a need to conduct more longitudinal designs which assess both traditional face-to-face bullying and cyberbullying from early childhood into late adolescents. Such investigations are important as many studies conducted on cyberbullying do not account for previous levels of traditional face-to-face bullying, despite the perpetration and victimization of these behaviors being highly correlated (Wright and Li, 2013a; Ybarra et al., 2007). It is also important for this research to assess children in early elementary school since children are beginning to utilize electronic technologies at a younger age (Madden et al., 2013), which places them at risk for cyberbullying, given the positive correlation between these behaviors and Internet usage (Ybarra et al., 2007).

Cyberbullying is not a concern only for researchers, educators, and youths themselves, but also for our communities. Educational curriculum should include information about cyberbullying, digital literacy, and citizenship as well as positive uses of electronic technologies (Cassidy et al., 2012b). Curriculum should also focus on empathy, self-esteem, and social skills. Schools should also aim to improve school climate through learning students' names, recognizing and rewarding good behavior, and staying technologically savvy (Hinduja and Patchin, 2012). The code of conduct at the school should also address appropriate technology usage and all adults in the school should advocate and enforce these policies.

Parents serve an important role in addressing cyberbullying. Although parents should "join forces with educators," they also need to gain an awareness of the technological environment, and an understanding of the behaviors their children might engage in through that environment (Cassidy et al., 2012a). Parents are also important models for appropriate online behavior. As indicated in the first section of this chapter, many cases of cyberbullying suicide took parents completely by surprise. Therefore, parents should engage in open communication about appropriate technology usage, including discussing with their children the amount of time that they should spend online and the ways they should act in this environment.

It might be difficult to understand how cyberbullying is also a community-problem; in our communities, many of us are bystanders. If we notice someone who needs help, we should help them, instead of expecting others to do it. Helping others models appropriate behaviors for the whole community. Cyberbullying legislation has also been slower to develop in some areas of the world. Such legislation has been helpful for addressing cyberbullying outside of the school (Cassidy et al., 2012b). Cassidy and colleagues note that cyberbullying laws should be part of the solution, but that it is not the whole solution. They advocate for the reformulation of cyberbullying laws which further core social values. Electronic communication has become the standard means of communication for youths as well as adults. As such, many forms of social interactions and social communications have transferred to this medium, including cyberbullying. Attacks in cyberspace are just as powerful as face-to-face attacks, sometimes even more so, because of the persistence of the attack. Society needs to recognize this threat and deal with it as a powerful menace, which can affect everyone. Cyberbullying is not going away. It will remain with us for as long as we interact through this interconnected electronic society.

Chapter 55

SCHOOL AND PEER CONTEXTS OF BULLYING

Michelle F. Wright*

Masaryk University, Faculty of Social Studies

ABSTRACT

This chapter synthesized recent research on bullying and victimization in educational settings. The chapter drew on literature related to the impact of the school context, particularly school climate and school characteristics, on youths' involvement in bullying, as victims and perpetrators. This section of the chapter discussed studies on the effect of school size, class size, racial and ethnic minority composition, and school location on school bullying. School climate was also examined, specifically teachers' attitudes and students' perceptions of teachers' attitudes, and how such climates relate to school bullying. At the end of this section, school-based preventive intervention programs are described, highlighting the effective components of these programs. The second part of this chapter focused on peers' roles in school bullying. It also covered bystanders, peer clustering, peer ecology, and peer status, and how these impact school bullying involvement. This section concludes with the effectiveness of peer-based preventive intervention programs. The final section of the chapter provided recommendations for schools, parents, and youths. The research shared in this chapter utilized cross-sectional, longitudinal, qualitative, and quantitative research methodologies. It also incorporated research across multiple disciplines, including psychology, sociology, education, social work, and anthropology. The research featured is also international to provide a broad overview of school bullying across the world.

Bullying is a global problem, reported in multiple countries throughout the world. The literature on this topic has been evolving over the last 25 years. This research has provided an important framework for understanding the nature, extent, causes, and consequences of bullying. Usually perpetrated in group settings, bullying is likely to occur in schools. Much of the attention given to school bullying by the public has been the result of school shootings. Although school shootings are rare, a hypothesis to explain these shootings is that such events

* Corresponding Author's Email: michelle.wright@mail.muni.cz

are perpetrated by youths in retaliation for experiencing school bullying. The April 20th, 1999 Columbine High School shooting perpetrated by Eric Harris and Dylan Klebold brought greater awareness of school bullying. To understand their motivations for the shooting, interviews were conducted among their group of friends, and findings revealed that this group was frequently bullied, though other schoolmates indicated that Eric and Dylan were also bullies. Research partially supports the victimization and retaliation hypothesis. For instance, Nansel and colleagues (2003) utilized a nationally representative sample of 6th through 10th graders in the United States to understand the relationship between bullying and more serious violence. Their results indicated that more serious behaviors, like fighting or carrying a weapon to school, were strongly related to both bullying perpetration and victimization. Since 1999 other school shootings have occurred, along with many high profile cases of school bullying victims committing suicide, bringing additional awareness to this topic. Some of this awareness has resulted in bullying programs on school campuses and television commercials dedicated to how youths can prevent school bullying.

Although the 1999 Columbine school shooting has brought more awareness to the problem of school bullying, the systematic study of school bullying began in the 1970s. Olweus's 1973 book, *Aggression in the Schools: Bullies and Whipping Boys*, triggered research on school bullying in Scandinavian countries. When the book was translated into English in 1978, research on school bullying in other countries began to burgeon. No more than 10 years after the English-language translation was available, a European conference was held on school bullying and Olweus launched a preventive intervention campaign aimed at preventing bullying in Norway among primary and secondary school youths. Shortly after this time, in the early 1990s, northwestern European countries, like England, Wales, and Scotland, launched preventive intervention programs, modeled after Olweus's program in Norway. Research and awareness at this time was also sparked outside of Europe in Canada, the United States, Australia, and New Zealand. Despite being a bit slower to develop, there is also a focus on school bullying in Asia, and work is currently underway in Africa and South America. Taken together, it appears that global efforts are being undertaken to eliminate school bullying.

Ample research attention has been given to the relationship between school bullying and the individual-level correlates of bullies and victims. However, it is important to also understand the effect of schools and peers on youths' involvement in school bullying. This chapter draws on interdisciplinary research from psychology, social work, education, sociology, and anthropology to describe the role of schools and peers in school bullying. There are two parts of this chapter:

- (1) One part focuses on the role of schools. This part begins with an overview of the literature revealing the relationship of school characteristics and school climate to youths' involvement in school bullying. In the next section, school-based preventive intervention programs are described.
- (2) The second part of the chapter focuses on peers. The next two sections of the chapter describe how peers' characteristics influence school bullying and the role of the bystander. The next section describes preventive intervention programs. The chapter concludes with recommendations for schools, parents, and youths.

THE SCHOOL ENVIRONMENT

School Characteristics

Although more research attention has been given to individual-level characteristics associated with school bullying, some studies have highlighted the importance of investigating school-level predictors (Gottfredson, 2001). Schools possess various characteristics that might be protective factors or risk factors that are related to youths' bullying involvement as perpetrators and victims. Some characteristics investigated in the literature include grade level differences, size of student enrollment, class size, teacher-student ratio, racial and ethnic composition, and school location. In this literature, researchers are concerned with whether the location and timing of school bullying can predict when youths will be involved in these behaviors.

Grade level and age are influential predictors of school bullying. Hanish and Guerra (2004) found that school bullying increased with age in primary school, but these behaviors declined as youths got older and reached the later years of secondary school (Rigby, 1996). However, when youths continue to be bullies and victims in secondary school, their rates of bullying and victimization are more stable and permanent over time (Hanish & Guerra, 2000; 2004). Therefore, it has been suggested that older bullies target victims more discerningly and repetitively than younger bullies. In addition, the transition from primary school to secondary school might account for such findings as youths begin attending a new school, which is usually larger. While school bullying decreases with age, it is also at its peak at the beginning of the high school years (Parada, 2000; Pellegrini, 2004). Many of these studies do not distinguish between the different types of school bullying, including physical forms, verbal forms, and social forms. Delineating bullying behaviors according to these forms, Griezel and colleagues (2012) found that younger youths were likely to perpetrate physical bullying when compared to older youths. Other research suggests that relational forms of bullying increase with age as physical forms of bullying are replaced by these more subtle and complex forms of school bullying (Losel & Bliesner, 1999). Similarly, using a Turkish sample of 12-17 year olds, Sirvanli-Orzen (2006) found that relational victimization decreased by age in girls and that experiencing teasing decreased by age for boys. Marees and Petermann (2010) also found negative correlations between age and victimization.

Research findings on the association of school size and class size on school bullying are inconsistent. Some studies have not found any relationship between the involvement in bullying as victims or bullies and school size or class size (Khoury-Kassabri, Benbenishty, & Astor, 2005; Mellor, 1999; Olweus, 1991; Wei, Williams, Chen, & Chang, 2010; Whitney & Smith, 1993). On the other hand, other studies have found that school bullying problems were greater at larger schools and in larger classes (Leung & Ferris, 2008; Stephenson & Smith, 1989). In contrast, O'Moore's and colleagues' (1997), Ma's (2002), and Klein's and Cornell's (2010) findings revealed that, although larger schools had more disciplinary problems, rates of school bullying were lower at these schools. Somewhat supporting these results, Wolke and colleagues (2001) found that smaller schools and classes increased school bullying in English schools but not German classes. Blatchford's and colleagues' (2003) results also revealed that smaller classes had higher incidences of school bullying. There have been some explanations (e.g., larger schools have more and better resources) proposed for why school size and class size

might contribute to school bullying, although a detailed description of such theories and research is outside the scope of this chapter (see Klein & Cornell, 2010 for review).

Racial and ethnic composition of schools has little effect on school bullying frequencies. In this literature, most studies have found that racial and ethnic make-up of schools has no effect on school bullying (Boulton, 1995; Junger, 1990; Lumeng, Forrest, Appugliese, Kaciroti, Corwyn, & Bradley, 2010; Moran, Smith, Thompson, & Whitney, 1993; Nguy & Hunt, 2004; Siann, Gallagher, Glissow, & Rawson, 1994; Whitney & Smith, 1993). However, some researchers (Vervoort, Scholte, & Overbeek, 2010; Wolke et al., 2001) have found relationships between these variables, but the associations were weak.

Like research on the effects of racial and ethnic minority composition, class size, and school size on school bullying, conclusions regarding the association between school location and these behaviors are also mixed. In some of these studies, researchers (e.g., Mellor, 1999; Olweus, 1991) have found no relationship between urban location or socioeconomic status and bullying, whereas others (e.g., Stephenson & Smith, 1989; Whitney & Smith, 1993; Wolke et al., 2001) have found greater amounts of bullying in inner-city, and low socioeconomic areas. Researchers have also investigated the location within schools and its effect on school bullying. School bullying occurs more frequently in areas with fewer rules, larger areas, minimal adult supervision, where the ratio of students to teachers is high, and on the playground (Collins, McAleavy, & Adamson, 2004; Craig, Pepler, & Atlas, 2000; Frost, 1991; Mellor, 1990; Smith & Shu, 2000; Whitney & Smith, 1993; Wolke et al., 2001). Youths are also likely to be bullied in the hallway, the bathroom, and the classroom (Bradshaw, Sawyer, & O'Brennan, 2007; Collins et al., 2004; Espelage & Asidao, 2001; Fite, Williford, Cooley, DePaolis, Rubens, S. L., & Vernberg, 2013; Vaillancourt et al., 2010). The school bus is also another location in which youths report being bullied (Allen, Young, Ashbaker, Heaton, & Parkinson, 2003; deLara, 2008; Raskauskas, 2005).

School Climate

Defined as the quality of schools' social environment, school climate, "the inner workings of the school," includes the social organization of the school, the social relationships between teachers and students, and the cultural system or norms and values in the school (Cohen, McCabe, Michell, & Pickeral, 2009; Ma, Stewin, & Mah, 2001). School climate is an important school-related variable to investigate because it relates to general school disorder (Gottfredson, Gottfredson, Payne, & Gottfredson, 2005). Positive school climate includes schools that are considered safe, consistent with rules and policies, have high parental involvement, supportive student-teacher interactions, are engaging, collaborative, and respectful (Kasen, Berenson, Cohen, & Johnson, 2004; Ma, 2002; National School Climate Council, 2007; Reis, Trockel, & Mulhall, 2007). Such a climate boosts positive peer interactions, reduces peer rejection, and improves psychosocial development (Loukas & Murphy, 2007). When school climate is positive, the school environment also includes less school bullying and victimization (Nansel et al., 2001; Gottfredson et al., 2005; Welsh, 2000). Therefore, positive school climate has a major role in decreasing the likelihood of perpetrating school bullying (Bandyopadhyay, Cornell, & Konold, 2009; Klein, Cornell, & Konold, 2012).

Poor school climate relates to less concern regarding bullying-related attitudes among teachers and students (Whitney & Smith, 1993). When teachers are less tolerant of school

bullying, they are more likely to discuss these behaviors with students, easily recognize bullying behaviors, and more often intervene, with each of these relating to less school bullying. Furthermore, teachers, who are better able to label bullying behaviors and articulate problems with bullying found in their school, show greater concern for controlling and preventing school bullying (Stephenson & Smith, 1991). School climate might also affect youths' perceptions of their schools' ability to handle bullying. Such a proposal is corroborated by research evidence indicating that youths who reported lower school climate felt that teachers were uninterested in stopping school bullying (Rigby, 1996; Harris, Petrie, & Willoughby, 2002). Measuring different types of multiple school climate variables, Harel-Fisch and colleagues (2011) found that the student-teacher relationship was one of the strongest predictors of school bullying perpetration. Taken together, the research on school characteristics and school climates has led researchers to develop a number of preventive intervention programs, which have been implemented within the school environment and tested for effectiveness.

School-Based Preventive Intervention Programs

Many school-based preventive intervention programs focus on the entire school. These "whole-school approaches" are designed to reduce or eliminate school bullying (Farrington, 1993). The primary objectives of these programs are to increase the awareness of school bullying from the perspectives of educators, parents, and students by improving school climate. Another aim of these programs is to establish and implement clear anti-bullying policies about the norms and acceptability of school bullying. Ultimately, the whole school is involved in these types of prevention programs. After the program is in place, the whole school aspires to reduce school bullying, improve participation and involvement in the school environment, focus on creating greater collaboration and support, and increase the school communities' bond. Overall, the school becomes more communal, resulting in decreases of all problem behaviors at the school, especially bullying. Research attention has been given to the association between the whole school approach and school bullying, with results indicating that there are reductions in bullying over the years (Arora, 1994; Clarke & Kiselica, 1997; Olweus, 1994). There are many examples of whole-school approaches to preventing bullying, including Bully Proofing Your School and the Bullying Prevention Program, which are described next.

Bully Proofing Your School is a comprehensive program implemented in an effort to improve the school climate of elementary schools through the creation of norms that any type of school bullying is not acceptable (Garrity, Jens, Porter, Sager, & Short-Camilli, 1994; Garrity & Jens, 1997). This program was modeled after Olweus's core intervention program from 1978, and one of its major goals is to create safe and secure school environments. In this program, facilitators provide training and support to school personnel and parents in an effort to ensure that the program is maintained overtime. The whole school works together to develop disciplinary policies concerning school bullying, which emphasize caring and the consequences of bullying behaviors. The nature of bullying and ways to avoid victimization are implemented into classroom curriculum through discussion, role-playing, books, videos, and skits. Once the program is implemented, school personnel, students, and parents develop not only an awareness of bullying but also accountability for creating solutions and confidence in using preventive strategies for reducing school bullying. Garrity and Jens (1997) found that the Bully Proofing Your School program was effective for producing communal school environments that are

more caring, and that experience decreases in school bullying and the fear that these behaviors might occur. Working together, these improvements create a more positive school climate. Similarly, Beran and colleagues (2004) found that schools with longer durations of the Bully Proofing Your School program had more positive attitudes toward victims when compared to schools with shorter program durations.

Olweus's (1991; 1994; 1997) Bullying Prevention Program is one of the most researched antibullying programs. This program also aims to improve school climate by emphasizing and creating warm interactions, positive interest, and high levels of involvement from all adults inside and outside of the school. In addition, the Bullying Prevention Program clearly describes unacceptable behaviors, sets firm rules for negative behaviors, and increases monitoring of students in the cafeteria and on the playground. This program aims to increase awareness of school bullying, to provide education about the types of these behaviors, increase adult involvement in the school and outside of the school, develop clear guidelines for rules and consequences for negative behaviors, and to support and protect victims. To implement these objectives, the program includes all adults in order to bring awareness of school bullying and to highlight the importance of their involvement in prevention efforts. Next, school personnel are administered a survey to understand the nature and extent of the problem at a particular school. The whole school is then recruited to oversee the implementation of the program. Classrooms develop antibullying classroom rules and hold frequent meetings on school bullying. The Bullying Prevention Program reduced bullying incidences in 42 Norwegian schools over two years (Olweus, 1994). The program was also effective for reducing vandalism, fighting, stealing, drinking, and truancy. School climate was also improved as well as classroom order, social relationships, and students' attitudes toward school and schoolwork. Recent research (e.g., Jenson, Brisson, Bender, & Williford, 2013; Low, Brown, Smith, & Haggerty, 2014) suggests that the Bullying Prevention Program is still effective for improving school climate and reducing school bullying.

THE EFFECTS OF PEERS

Peers' Characteristics

As an integral part of school climate, youths' attitudes toward school bullying predict the levels of bullying within the school (Boulton, Bucci, & Hawker, 1999). Generally, youths have neutral attitudes toward school bullying or antibullying attitudes, and many have a hard time understanding why children bully others (Boulton & Underwood, 1993; Stevens, Van Oost, & Bourdeaudhuij, 2000). Most youths find school bullying unpleasant, with a smaller percent of students being indifferent to these behaviors (Charach, Pepler, & Ziegler, 1995). Boulton and Flemington (2002) found that more negative attitudes toward school bullying were related to less bullying among English secondary school students. Such relationships were also found among Greek (Boulton, Lanitis, Manoussou, & Lemoni, 1997) and Swedish (Boulton et al., 1999) students. Although many youths hold negative attitudes toward school bullying, their support for the victim decreases with age (Rigby & Slee, 1992). Therefore, it is not surprising that youths rarely intervene when they witness school bullying (Boulton & Underwood, 1993; Charach et al., 1995; Smith & Shu, 2000; Stevens et al., 2000; Whitney & Smith, 1993). Observational studies also support youths' self-reports that they do not intervene in school

bullying (Pepler, Craig, & Roberts, 1989). Craig and Pepler (1995) suggest that this lack of intervention might reinforce bullies. Utilizing another observation methodology, Craig and Pepler found support for this hypothesis. Youths reinforced the bullies' behaviors in 81% of bullying episodes. In addition, peers were more respectful and friendly to bullies than to victims, providing support for the peers' alignment with and reinforcement of bullies. Such behaviors might potentially prolong bullying episodes. O'Connell and colleagues (1997) also found that 31% of youths in their sample admitted that if someone they disliked was being bullied they would join in as well. Other characteristics of the peer group affect school bullying and victimization. When peers were isolated and disliked by their peers, they were more likely to perpetrate bullying or be victimized (Fitzpatrick, Dulin, & Piko, 2007; Newman, Holden, & Delville, 2005; Schafer, Korn, Brodbeck, Wolke, & Schultz, 2005; Veenstra, Lindenberg, Oldehinkel, De Winter, Verhulst, & Ormel, 2005; Williams & Guerra, 2007). Affiliation with delinquent peers is also a consistent risk factor associated with bullying behavior (Mouttappa, Valente, Gallaher, Rohrbach, & Unger, 2004; Ybarra, Espelage, & Mitchell, 2007).

The function and importance of the peer group changes dramatically in early adolescence (Crockett, Losoff, & Petersen, 1984; Dornbusch, 1989). Therefore, belonging to the peer group becomes a stronger goal for many youths. During this time, peer dominance hierarchies also increase, and many youths become concerned with social status as peer groups become divided and issues of acceptance and popularity become increasingly important (Corsaro & Eder, 1990; Eder, 1985). Eder (1995) found that toughness and aggressiveness were important determinants of status for boys, whereas appearance was central to girls' social status. Therefore, because many adolescents desire to "fit in" with their peers, some researchers (e.g., Pellegrini, Bartini, & Brooks, 1999; Rodkin, Farmer, Pearl, & Van Acker, 2000) have proposed that the pressure to gain peer acceptance and status might increase bullying in order to demonstrate superiority over other students. Support for this proposal was found by Espelage and colleagues (2001). Their findings revealed that adolescents who wanted to "fit in" adopted bullying behaviors, like teasing, in order to gain more power and a higher social standing. Researchers have conceptualized of two related forms of high peer status, perceived popularity (i.e., high peer status characterized by social prestige, social power, and social visibility) and social preference (i.e., peer acceptance or peer liking), which are differentially linked to school bullying (Bukowski, 2011; LaFontana & Cillessen, 2002; Parkhurst & Hopmeyer, 1998). Social preference is related to prosocial behaviors, whereas perceived popularity is associated with physical forms of bullying in childhood and relational forms of bullying in adolescence (Cillessen & Marks, 2011; Cillessen & Mayeux, 2004). There is also research evidence that youths, particularly adolescents, form goals concerning their desired peer statuses (Covington, 2000; Dweck & Leggett, 1988). Due to their desire to be more popular, adolescents develop goal-directed attitudes and behaviors in order to achieve this higher status. Research evidence demonstrates that adolescents with perceived popularity goals were also more likely to perpetrate school bullying, whereas adolescents with social preference goals did not (Li & Wright, 2013; Wright, Li, & Shi, 2014).

Bystanders

Many youths are uninvolved in school bullying, and around 85% witness these behaviors without directly being involved (Charach et al., 1995; Craig & Pepler, 1997; Hawkins, Pepler,

& Craig, 2001; O'Connell et al., 1999). Someone who witnesses one child bully another is referred to as a bystander. Like the consequences associated with bullying and victimization, bystanders can also experience anxiety, depression, guilt, and helplessness (Rivers, Poteat, Noret, & Ashurst, 2009). Bystanders serve three different roles during a bullying incident. In the first role, bystanders do not get involved, only watching the bullying incident occur. Although the bystander isn't instigating the situation, the bystander is giving the bully the attention he or she craves. Not intervening, and remaining silent, might give the impression that it is okay for the bully to continue his or her behavior. In addition, bystanders might not intervene because they fear becoming the new target of the bully's attacks. The second role involves the bystander instigating the bully by laughing, cheering, and making comments throughout the bullying situation (Nickerson, Mele, & Princiotta, 2008). They might even join in on the bullying. The last role is when bystanders directly intervene by discouraging the bully, defending the target, or redirecting the situation. Many bystanders get help from their peers by rallying support to stand up against the bully or to tell an adult about the bullying incident. They will also reach out to the victim to let him or her know everything is okay. Between 10% and 20% of youth intervene when they witness school bullying (Salmivalli, Lagerspetz, Bjorkquist, Osterman, & Kaukiainen, 1996). Research evidence also reveals that the presence of bystanders can influence rates of bullying. Felson (1982) found that verbal disputes escalated quicker when bystanders were present, especially bystanders of the same gender. Utilizing an experimental design, Howard, Landau, & Pryor (2014) found that moral disengagement and positive attitudes concerning bullying were greater when youths were exposed to a passive bystander. In the Cyberball task, these youths were also less willing to include the victim in the game. Due to the strong impact of peer support and contributions to school bullying, many peer-based preventive intervention programs have been developed.

Peer-Based Prevention Programs

Lots of attention has been given to the development of peer support interventions which harness youths' potential to tackle school bullying. These programs, like the Students' Welcomers Program and Students' Antibullying Committee, also utilize the whole-school approach to bullying prevention, but focus more attention on the student component. Peer support programs are structured systems used to foster youths' abilities to help reduce school bullying. In primary schools, students who appear lonely are befriended or become buddies with a trained student (Smith & Samarra, 2003). Secondary schools utilize similar schemes but activities typically focus on trained students doing some type of activity with their peers, such as running a lunchtime club, offering support, listening to students' problems, doing group work with a tutor group, or working as mediators to resolve conflicts (Cowie & Wallace, 2000; Fernandez, Villaoslada, & Funes, 2002; Smith & Watson, 2004). Training of the students usually involves learning how to actively listen and respond genuinely and authentically to the needs and feelings of those seeking help. Programs which focus more attention on the peer support system are effective for creating more communal school environments. Findings from one peer support program revealed that school bullying was significantly reduced among 9th graders who had a greater likelihood of being victims (Peterson & Rigby, 1999). Naylor and Cowie (1999) also found that implementing a peer support system had positive impacts on improving the social organization of a school and for reducing school bullying incidences.

Follow-up research by Cowie and colleagues (2002) demonstrated that these effects were still observed two years later. Testing the effectiveness of the ChildLine Peer Mentoring System, Smith and Watson (2004) found that youths in this program generally found it helpful in both primary and secondary schools. Other research by Cowie et al. (2008) found that peer support schools helped students feel that their schools were safer, friendlier, and more engaging. These students also worried less about school bullying.

CONCLUSIONS AND RECOMMENDATIONS

School bullying should not only be a concern for schools, but students, parents, and communities. Research (e.g., Bandyopadhyay et al., 2009; Cohen et al., 2009; Gottfredson et al., 2005; Kasen et al., 2004; Klein et al., 2012; Ma et al., 2001; Reis et al., 2007) demonstrates the effects these individuals have on school climate, which is important for reducing school bullying. Many schools are embracing and implementing the characteristics necessary for positive school climate by increasing their participation and involvement with reducing school bullying as well as establishing supportive and collaborative relationships with students and parents. More research is needed to understand and clarify the relationships of school characteristics and school climate on school bullying. Parents and adults from schools should not only talk about bullying with youths, they should also help youths recognize when situations are actually school bullying versus playful teasing and everyday conflicts (Arora, 1994; Clarke & Kiseica, 1997; Garrity et al., 1994; Olweus, 1997). Each of these considerations is important as they help to empower youths to intervene when they witness school bullying. Such empowerment is helpful for reducing school bullying as peer support systems are accepted as valuable systems for reducing school bullying. Bystanders should be able to recognize when they need to help and how they can help, empathize with the victim, and accept responsibility for intervening (Nickerson et al., 2008; Salmivalli et al., 1996). To support bystanders' abilities to intervene, adults should role-play different bullying situations and provide information about how to help and act. In conclusion, as a community, we must take school bullying seriously and consider it as harmful and unwanted behaviors. Together we must convey that school bullying is wrong and never justified. Everyone should feel safe and never be abused by anyone. Ultimately, "it takes a whole village to raise a child," and such a phrase has application to school bullying as these behaviors are a global concern, warranting everyone to do their part to end them.

ABSTRACT

Background: Cyberbullying refers to an indirect and covert form of aggression, carried out through the use of new technologies, and exhibiting distinct features from those found present in traditional bullying, and has been acquiring its own space of analyses and research; still, it maintains an inevitable proximity with the second, namely, the negative impact on the victim, both the person and the student, with consequences on academic performance, among other aspects.

Purpose: This piece reviews some of the most relevant studies on cyberbullying, its assessment and relation with personal (self-esteem, age, sex, ethnicity and type of aggression) and contextual (family, school context and peer group) variables, as well as with several aspect related to academic context, particularly, students' engagement in school and academic success. Considering the expected link between bullying and cyberbullying, some studies on the first form of aggression were included in this review, as they may be considered a theoretical referential in this subject.

Conclusions: Cyberbullying is a recent and important phenomenon, linked to the inclusion of new technologies in daily life. There are, however, some gaps in research carried out on this issue, which presents different features from those that characterize traditional bullying. Similarly to bullying, studies suggest that cyberbullying presents negative impact both on students and academic success. Students' engagement in school plays an import role in the occurrence of aggression-victimization behaviors and appears to be a valorous strategy in cyberbullying prevention.

Keywords: cyberbullying, students' engagement in school, personal variables, contextual variables, academic performance.

INTRODUCTION

Cyberbullying appeared in the literature to identify an indirect form of aggression, which occurs through the use of new technologies (Ortega-Ruiz & Núñez, 2012), and currently occupies its own ground of analyses and investigation. Research has been establishing a link between the determinants and effects of in person bullying and cyberbullying (Almeida, Caurcel, & Machado, 2006; MacGriemel, Finger, Bodkin-Andrews, Craven, & Yeung, 2012; Jose, Kljakovic, Scheib, & Notter, 2011; Low & Espelage, 2012); cyberbullying exhibits particular features, when compared to traditional bullying behaviors, still, it is likewise a disturbing element with impact on academic success.

Data on wellbeing during childhood, published in the *Innocenti Report Cards* (as cited in Quental & Veiga, 2010) indicated that 40% of the children surveyed in Switzerland, Austria and Portugal, were victims of bullying, stressing Pereira's findings (2008): a considerable increase in situations of aggression and victimization in Portuguese schools, where one in each five children indicated being continuously victimized by their peers.

This article reviews the most relevant studies on cyberbullying and its relation with several aspects associated with academic context, focusing, particularly, the relationship between cyberbullying and students' engagement in school, a construct which has been in the center of discussions about school institutions and their students. Specific studies about bullying, that may contribute to the understanding of cyberbullying, are also presented, and may work as theoretical referential or add suggestions for empirical research.

CYBERBULLYING: CONCEPTUALIZATION AND ASSESSMENT

Cyberbullying and, more traditionally, bullying in school context, constitute occurrences that have called the attention of the educational community, due to their adverse effects on the participants, either individual (self-esteem, self-concept) or scholar – achievement and behavior (Caldeira & Veiga, 2011). The adoption of the expression *bullying* to refer the perpetration, by a *bully*, of hostile behaviors toward a *victim*, intentionally and continuously throughout time, and, often, witnessed by active or passive bystanders, is due to Olweus (1994).

Peer aggression may take several forms, direct — physical, including kicking and beating, and verbal, like calling offensive names —, indirect such as exclusion from groups or, more recently, virtual, through the internet (blogs, emails, websites) or other means of communication like the telephone. The virtual mean stands out not only by how it occurs, requiring the use of new technologies, but also because of the change in the witnesses' role.

Both cyberbullying and bullying encompass a series of behaviors likely to negatively affect the student exposed to those types of aggression (Caldeira & Veiga, 2011; Veiga, 2007, 2012), as well as the other participants. Vanderbilt and Augustyn (2010) suggest that bullies and witnesses are marked by the effects of the aggression, nevertheless, must be considered as participants in the occurrence.

Santos and Veiga (2012) observed a superiority of verbal aggressions, compared with the other forms. Holfeld and Grabe (2012) found that only 64% of the victims report the incidents (primarily to their parents and peers), being the percentage lower, 60%, in the case of witnesses.

The assessment of this type of aggression relies on some instruments that have been developed for specific studies, although literature suggests that the need to study the relation between bullying and cyberbullying validates the use of instruments allied to the first type of aggression.

There may be found some studies where specific instruments, directed toward cyberbullying, were created for that purpose (Griezel, Craven, Yeung, & Finger, 2008; Heirman & Walrave, 2012; Stewart, Drescher, Maack, Ebesutani, & Young, 2014), being that, many of them were adapted from pre-existent instruments, applied in bullying assessment. Most of the instruments are self-report questionnaires, answered by the students, using Likert-type scales; the items focus is, frequently, students' perception about cyberbullying (*Cyberbullying Scale* - Stewart, Drescher, Maack, Ebesutani, & Young, 2014), and their own experiences (*Cyberbullying Student Survey* - Li, 2010). Some questionnaires present specific forms, for the cyber-victims and the cyber-bullies (*Cyberbullying Scale - CBS*, Topçu, 2008). Projective methods are also found, like in the study carried out by Gomez-Garibello, Shariff, McConnell and Talwar (2012). Other studies attend to the teachers' perceptions, for example, the one by Li (2008), using the *Teachers' Perceptions about Cyberbullying Questionnaire*.

Given their relevance and psychometric qualities, validity and reliability, some assessment instruments are presented:

Safe Schools Survey (Ontario Ministry of Education). Included cyberbullying in its 2nd edition (2004), being composed by 11 items, distributed by eight sections: students' perceptions, inclusion, incidents relating to victimization, incidents relating to perpetration, responses to bullying, reporting bullying, use of technology, and general comments.

Cyberbullying Student Survey (Li, 2010). Consists of four parts: demographic data, students' behaviors and beliefs related to cyberbullying, and students' opinions about online behaviors in general.

Revised Adolescent Peer Relations Instrument – Bully and Target (Griezel, Craven, Yeung, & Finger, 2008). Composed by 61 items, responses in a 6-point likert-type scale (from 1, never, to 6, everyday).

Teachers' Perceptions about Cyberbullying Questionnaire (Li, 2008). Questionnaire based on the work of Siu (2004) — *Teachers' Attitude about Bullying Questionnaire* — composed by 26 items, focusing on teachers' perceptions about cyberbullying (from 1, totally disagree, to 5, totally agree).

Griezel et al. (2008) point out some limitations in cyberbullying assessment: little is known about the structure of the cyberbullying construct implying that the instruments applied are not specifically designed for it; using one or two items for the assessment of multidimensional constructs; weaknesses in the research carried out include the sample size, the psychometric fragility of the instruments and even the theoretical approaches.

Violence in school context — and particularly *bullying*, in both its traditional and the most recent cyberbullying form — has been investigated in relation to a number of factors, intrinsic to the student and contextual. Some studies on the relation between individual and contextual variables and the occurrence of cyberbullying are introduced.

CYBERBULLYING AND PERSONAL VARIABLES

Studies on the relation between cyberbullying and personal variables, such as self-esteem, sex, ethnicity and type of aggression are presented.

The relationship between cyberbullying experiences and *self-esteem* was studied by Patchin and Hinduja (2010), with 1963 middle school students, and a moderately significant relation was found between bullying experiences and self-esteem. Those students with cyberbullying experiences (both as a victim and as a bully), showed lower self-esteem, when compared with their peers with little or none experience with that type of aggression.

Several studies found that aggressive behaviors tend to decrease with *age* and as students' progress in schooling, indicating a greater fragility of younger students (Olweus, 1994; Santos & Veiga, 2012). The prevalence of aggressions in school context justifies serious reflection and investing in intervention procedures. Jose et al. (2011) studied adolescents aged between 11 and 16 years, in the context of the *Youth Connectedness Project* (YCP), carried out in New Zealand, and found that the occurrence of aggressions (either in person or virtual) remains stable during two years. Holfeld and Grabe (2012) studied middle school students' cyberbullying experiences, and concluded that one in each five students had been bullied in the last year. These authors express the variability found in the literature on the prevalence of cyberbullying, what seems due to methodological and sampling differences: a review by Patchin and Hinduja (2010) found a variation between 5,5% and 72% (mean of 24,4%) in the prevalence of cyberbullying. Still, according to these authors, this type of occurrence is significant and tends to increase all over the world. Research also indicates that bullies tend to preserve such attitudes as adults, and their children, frequently, also become bullies. This seems also true concerning to victims (O'Connel, Peppler, & Craig, 1999).

Differences according to *sex* appear contradictory, in research; some authors found differences in cyberbullying in favor of boys, either bullies or victims (Wang, Iannotti, & Nasel, 2009); other found a superiority in favor of girls (Holfeld & Grabe, 2012 – as victims, bullies or witnesses); further others, found no differences between sexes (Williams & Guerra, 2007). Boys showed a higher probability to act as bullies, while girls to be victims, concerning to cyberbullying (Wang, Iannotti, & Nasel, 2009). Differences according to sex were also found by Arslan, Sevim, Hallett and Balci (2012), with a higher prevalence of boys acting as bullies. In the sample, 27% of respondents indicated having been bullied; 16% appeared as bullies; and 15% were both victim and bully. Zhou, Tang, Wei, Zhang and Morrison (2013) also found a higher probability of boys to be involved in cyberbullying occurrences, either as bullies or victims.

Considering *ethnicity*, a study by Wang, Iannotti and Nasel (2009) found a higher association of Afro-American adolescents to bullying behaviors (physical, verbal and virtual), and a smaller association with victimization. Low and Espelage (2012) investigated the differences between non-physical bullying and cyberbullying, according to ethnicity (and considering individual and family predictors), in adolescents from 5th to 7th grade, considering three different moments separated from each other by six months. In general, data suggests a higher prevalence of cyberbullying among Afro-American adolescents, in comparison with white students. In a study with 518 Canadian adolescents of either East Asian or European descent, of both sexes, aged between 12 and 18 years (7th-12th grades). Shapka and Law (2013) analyzed the differences in cyberbullying using a self-report questionnaire. Data was subjected

to regression analyses and suggested that East Asian adolescents were less likely to be involved in cyberbullying; East Asian adolescents were more likely to participate in cyber-aggressions for proactive (instrumental) than reactive (as a response to provocation) reasons, and the opposite was true for European descent adolescents. The superiority of proactive reasons, in East Asian adolescents, was significantly higher in males, compared to females. The authors confirm the correspondence of such results with the ones found in literature, and highlight the cultural impact on the drives underlying cyberbullying behaviors.

Attending to the *types of aggression*, in a study carried out by Santos and Veiga (2012), boys presented higher values in physical and verbal victimization, while girls showed higher scores in the social dimension of victimization, similarly to what was found by Olweus (1994), Craig (1998), Beane (2006), or Wang, Iannotti and Nasel (2009). In a study on cyberbullying behaviors, Feldman (2012) found that in adolescents who were simultaneously victims and bullies, the involvement in these type of behaviors was related to poorer psychosocial functioning and relations, compared to students who were solely victims or bullies, or were not involved in these type of behaviors.

CYBERBULLYING AND CONTEXTUAL VARIABLES

Some studies on the relation between cyberbullying and environmental variables are introduced, such as family, school context and peer group.

Family has arisen as a study context, in seeking for predictors for the occurrence of aggression behaviors. Studies on direct bullying suggest a relation between these type of behavior and conflicting or severe parental styles (Baldry & Farrington, 2000; Bowes et al., 2009; Olweus, 1994), as well as low parental monitoring (Vanderbilt & Augustyn, 2010; Veiga, 2007, 2012a). Family rules (too rigid or absent) appear associated with aggressive behaviors (Caldeira & Veiga, 2011; Smith & Sharp, 1998; Vanderbilt & Augustyn, 2010; Veiga, 2012a). In a study carried out by Low and Espelage (2012), family monitoring appeared related to high levels of cyberbullying at wave 3, though the use of substances, in white females. Non-physical bullying was related to high family violence and low parental monitoring, explained by hostility (in boys and white race subjects) and depressive symptoms (Afro-American boys). Wang, Iannotti and Nasel (2009) found that cyberbullying (similarly to bullying, physical, verbal, and relational), was also related to low parental support. Shapka and Law (2013) also attended to the relation between cyberbullying and parental behaviors (parental control, behavioral boundaries definition; parental solicitation, knowledge obtained from the children; children's disclosure, knowledge obtained from the children's spontaneous sharing) in East Asian and European descents youth. They found that high levels of parental control and low levels of parental solicitation were associated with low involvement in cyberbullying behaviors in East Asian participants, when compared to their European peers.

The belief that bullying behaviors could be punished by significant adults appeared related to non-participation in this type of actions, in a study by Hinduja and Patchin, (2013) with adolescents from 6th to 12th grades

Considering the variable *school context*, Stauffer, Heath, Coyes and Ferrin (2012) studied teachers' perception about the effects of cyberbullying on students, as well as the most effective strategies to address this type of aggression. Approximately ¼ of the teacher indicated

cyberbullying would have a small long-lasting negative impact on students, and less than half were in favor of formal prevention programs development. Teachers pointed out a few strategies for being more effective in responding to cyberbullying: increasing parental involvement, alerting students about the consequences for cyberbullying, and increasing effective consequences for cyberbullying occurrences.

Peer group assumes particular importance during adolescence. Some authors have confirmed the link between the adolescent's behavior and the one exhibited by his peers (Bray, Adams, Getz, & McQueen, 2003), which turned out present concerning cyberbullying behaviors, in a study carried out by Shapka and Law (2013). The amount of friends was associated with more bullying behaviors and lower victimization (verbal, relational, physical), result not found in cyberbullying, in a study developed by Wang, Iannotti and Nasel (2009).

ENGAGEMENT IN SCHOOL AND CYBERBULLYING

Students' engagement in school - SES is a concept that, in the context of intervention in cyberbullying, has been presenting a protective role (Low & Espelage, 2012; Mehta, Cornell, Fan, & Gregory, 2013; Shapka & Law, 2013; Veiga, 2012a; Zhou et al., 2013). SES may be characterized as a multidimensional construct, which encompasses students' thoughts, feelings and behaviours (Fredericks, Blumenfeld, & Paris, 2004; Furlong et al., 2003), or as the experience of centripetal connection of the student to the school (Veiga, 2012, 2013), including four components – cognitive, behavioural, emotional and agentic.

Researches discussed in the literature have found a relation between this concept and peer victimization (Seeley, Tombari, Bennet, & Dunkle, 2009; Wilson, 2004). Engagement has been addressed as a predictor of several behaviors (better grades, less behavior problems) and is likely to be influenced by numerous variables, both personal and contextual. These types of relations are presented.

Wang, Nansel and Iannotti (2011) emphasize that — if bullying carries a body of *personal* (for example anxiety, aggression, hyperactivity and behavior problems) and *schoolar effects* – some effects may be superior in the case of cyberbullying, such as depression and task disengagement. A study carried out by Arslan et al. (2012) found an association between exposure to cyberbullying (either as victim or bully) and low levels of *school satisfaction* and *academic achievement*, in 372 students from 2nd to 4th grades.

Studies on bullying, as the following, may lead to posing hypothesis about what may occur in cyberbullying situations (Low & Espelage, 2012; Shapka & Law, 2013; Veiga, 2012; Zhou et al., 2013). A study conducted by Bayar and Uçanok (2012), with 1263 high school students (mean age: 14,9), concluded that those students who were not implied in aggression situations showed more positive perceptions of their school and teachers, when compared with aggressive peers.

Mehta et al. (2013) analyzed students' engagement in terms of commitment to school (affective and cognitive dimensions) and participation (behavioral dimension), in order to investigate whether students' perceptions about bullying climate in school were associated with low levels of engagement. The author used a sample of 7058 9th grade students, from Virginia schools, 50% male. The results indicated that those students who perceive school as a place where bullying often occurs, are less engaged, affectively and cognitively, compared to those

who perceive less bullying situations. As for the relation between bullying perception and participation, there were no statistically significant results; however, the authors indicate that students who perceive a bullying climate show less participation in extracurricular activities. With regard to contextual variables, the authors noted that school size stands as a predictor of students' cognitive and affective engagement, result not found regarding behavioral engagement. This study concludes that those schools with more bullying situations reflect lower levels of students' engagement.

Various studies highlight that negative experiences related to peers — such as bullying (Battin-Pearson, Newcomb, Abbott, Hill, Catalano, & Hawkins, 2000; Ma, Phelps, Lerner, & Lerner, 2009), rejection (Buhs, 2005), or the lack of friends (Wentzel, Barry, & Caldwell, 2004) — increase the probability of school disengagement, conducting to school dropout and to the connection with disruptive peers (Battin-Pearson et al., 2000).

Other studies (Low & Espelage, 2012; Shapka & Law, 2013; Veiga, 2012; Zhou et al., 2013) have analyzed, more particularly, the relations between engagement in school variables and bullying. Hirschfield and Gasper (2011) found that affective and behavioral engagement predicts a decrease in *delinquency*, both in school context and overall. Wilson (2004), using a sample of 2,327 middle school students, found that sense of belonging is inversely related to *victimization*. Li and Lerner (2011) analyzed the effects of school engagement (behavioral and emotional) on school grades and *risk behaviors* (delinquency and substance use), and found that high levels of emotional and behavioral engagement were predictors of a minor risk of delinquent behaviors and substance use, being positively associated with better performances and less symptoms of depression.

Seeley et al. (2009), with a sample of 860 6th grade students, found a significant negative association between *victimization* and affective and cognitive engagement, contrary to cognitive engagement; the authors suggest that aggression victims are behaviorally and emotionally affected. Results also showed that engagement is a moderator variable of the impact of victimization on school attendance. Intervention Programs addressing victimization are suggested, and should include the promotion of students' engagement which, in turn, will support the increase in school attendance and academic success.

CONCLUSION

Cyberbullying, a type of covert aggression consumed through the use of new technologies, presents particular features and consequences (Low & Espelage, 2012; Shapka & Law, 2013; Veiga, 2012; Zhou et al., 2013). Cyberbullying appears related to low engagement in school and negative academic performance, besides its psychological impact, relating to low self-esteem. Hinduja and Patchin (2013) suggest the influence of social factors, such as family, school and peer group, on bullying behaviors, and propose intervention measures like implementing peer mentoring programs, at school, and parental monitoring, at home.

Although a negative *school climate* does not mean an increase in aggression situations, between students, Wilson (2004) highlights that the links experienced by the student, at school, may be among the aspects which better contribute to predict aggression and victimization, either in its direct or indirect form, through new technologies. Even though individual and family factors may be in the basis of cyberbullying, its continuity seems related to school

context (Santos & Veiga, 2012). Teacher-student relationship, school organization, and the forms how aggression situations are managed, stand out as factors affecting the students' behavior (Caldeira & Veiga, 2011), suggesting the need to structure a school environment oriented toward prevention and intervention in this type of situations. Literature (Shapka & Law, 2013; Veiga, 2012; Zhou et al., 2013) suggests several lines of action, such as the promotion of a safe environment, involving parents and teacher, and clarifying with the students' their conduct regarding cyberbullying behaviors.

Positive relations with *peers*, during adolescence, appear in the literature as relating to an increase in academic motivation (Furrer & Skinner, 2003), self-esteem (Furrer & Skinner, 2003; Keefe & Berndt, 1996), and academic performance (Veiga, 2012), aspects likely to be affected by the occurrence of direct (bullying) and indirect (cyberbullying) aggression experiences. Disengagement from school may act as a response to negative behaviors from peers, such as victimization and exclusion (Almeida, Lisboa, & Caurcel, 2007; Buhs, 2005; Veiga, 2012), with impact on engagement through time (Li et al., 2011; Simmons-Morton & Chen, 2009).

When considering the *prevention* of cyberbullying, family involvement appears emphasized (Shapka & Law, 2013; Veiga, 2012; Zhou et al., 2013), since aggressions occur by means of internet or mobile phones use, and parental supervision may be crucial. Students' disengagement assumes a relevant role in aggression-victimization behaviors and, therefore, the triggering of strategies pointing students' engagement in school is an important contribution to cyberbullying prevention.

Chapter 57

BULLYING AND MORAL REASONING. THE INFLUENCE OF LIFE VALUES AND CULTURE ON ITALIAN TEENAGERS' SELF-ASSERTION

Brighi Antonella*, Giancesini Giovanna and Melotti Giannino

Department of Education, University of Bologna, Italy

ABSTRACT

In the last 15 years literature on bullying has emphasized the role of systemic processes in aggressive interactions, as well as the interplay of cognitive and emotional mechanisms leading to antisocial behaviors. Indeed, as adolescents interact with a varied social world, their development entails the formation of different but systematic types or domains of social reasoning. Social situations require a balancing and coordination of different social, individual and moral considerations related to features of the context. In this chapter, we suggest a broader view of moral reasoning through the investigation of individual, culturally influenced, *life values*. In our non-representative sample of 801 Italian students the prevalence students who witnessed episodes of school bullying was around 75% and the most common type was direct, either verbal (offending, teasing, threatening) or physical aggression. Participating roles in bullying were coded into uninvolved (neutral) bystanders (56.8%), victims (37.1%) and bully/bully-victims (6.1%). Moreover, when we examined the relation between aggression and life values, our results evidenced, in addition to a general individualistic tendency for personal success, richness, and ambition; some values specifically pertained to adolescent bullies, as evidenced by little consideration for others' needs and desires, low respect of societal norms and little importance attributed to honesty. Bullies' self-assertion tendencies appeared even stronger in female than in males. These values may be supported by expectations of positive outcomes from the bullying behavior openly expressed by the peers' group (Brighi & Genta, 2010, Brighi et al., 2007) or perceived by the bullies. Only by taking into consideration the interplay between personal goals, life and cultural values a fuller theoretical understanding of peer aggression can be reached. Integrative models are thus needed to investigate both *moral cognition* and *moral affect* in children in relation to their participant roles in different forms of bullying (Arsenio & Lemerise, 2004; Malti & Latzko, 2010).

INTRODUCTION

Bullying has been originally defined as an aggressive behavior characterized by repetitiveness and imbalance of power between the perpetrator and the victim. It may take different forms, be either direct (physical or verbal) or indirect (isolation, rumors, humiliation etc) and take place in a physical social context (traditional bullying) and/or virtual (cyberbullying) environment. Although cyberbullying may sometimes be an extension of traditional bullying, some of its peculiar features suggest that it may have a very distinct causal pathway (Brighi et al., 2012). Bullying is indeed a social and relational process, involving children as bullies, victims, and bystanders, who can act as assistant or reinforcer of the bully as well as outsider or defender of the victim (Salmivalli, 1999). Indirect bullying is exquisitely relational and refers to harm within relationships caused by covert or subtle manipulative behavior, including isolation and social exclusion, threatening to stop talking (the “silent treatment”), or spreading gossip and rumors (Perren et al., 2012). Evidences show that it may create just as much or more damage than physical aggression among youth. As bullying is directed toward a specific victim, the roles of both targeted individuals and perpetrators are important in fully understand the phenomenon (Thornberg & Jundert, 2013). Gini (2005) found that while victims showed difficulties in social cognition tasks, bullies showed moral disengagement mechanisms, whereas defenders showed higher levels of moral sensitivity. His study especially evidenced the importance of social cognitive competencies in “*the complex circle of behaviors, attitudes and expectations* (p. 26) upon which bullying is based and the relevance of fine-grained classifications of bullying roles. A more recent study by Pornari and Wood (2010) showed that moral disengagement in both traditional peer aggression and cyber bullying is consistently associated with lower levels of moral emotions like guilt and shame and higher levels of emotions like pride or indifference respectively. While the concept of moral disengagement seems to account for the behavior of bullies and their lack of sense of guilt toward victims, it does not seem to explain differences among victims and control children. Finally, Perren & Gutzwiller-Helfenfinger (2012) have hypothesized cyberbullies to have stronger deficits in morality than traditional bullies only. Despite the evidence of the existence of mediating processes between the moral and the social domains in adolescence, a great deal of research has mainly focused on teens’ goal preference rather than on the more complex and general understanding of how moral values shared in the social context influence social goals and aggressive/antisocial behavioral choices. Bullying cannot be understood without considering the cognitive mediators (Arsenio & Lemerise, 2004; Guerra, Nucci & Huesmann, 1994) and moral issues involved in fairness, others’ welfare, and refraining from harming others for personal gain (Turiel, 1998, Arsenio & Lemerise, 2001; 2004). Proactive bullying, in particular, could be associated with individualistic and instrumental moral orientation (Bergeron & Schneider, 2005), as suggested also by Menesini, Nocentini & Camodeca (2013). Their study investigated the mediating role of personal values and moral disengagement (bully, victim, and bystander) in traditional and cyberbullying. Traditional bullying was assessed by means of a self-report measures, while a Portrait Values Questionnaire was used to assess 10 values in four dimensions according to the value system model by Schwartz (1992). Results showed that self-enhancement and self-transcendence moderately predicted cyber and traditional bullying respectively, while immoral and disengaged behaviors predicted both. Indirect effect

showed that self-enhancement and openness to change predicted both form of bullying through immoral behavior.

Moral Reasoning

Morality (including avoidance of victimization and aggression) and *autonomy* (involving individual goals) are often viewed as being in contrast, which is not necessarily true in social conflicts where a legitimate concern for the self is weighted with moral considerations, personal goals, projects and hobbies (Killen & Nucci, 1995). The pursuit of instrumental goals, per se, is not necessarily conducive of proactive aggression. To investigate how behavioral choices are associated to personal and social goals can have many important implications in addressing in which way proactive aggressive and non-aggressive teens differ on relational dimensions and moral development. Crick & Dodge (1996) found, in fact, that proactive aggression is associated more with instrumental ("I want this") than relational ("I want to be his friend") goals, although such a sharp contrast between the two seem too simplistic (Arsenio & Lemerise, 2001). According to Bandura's theory, internal mechanisms of self-regulation act as mediators between behavior and internal moral norms and moral emotions such as shame, feeling of guilt, self-blaming, keep the balance between our behaviors and our internalized moral norms and values. Gibbs' (2003) theory of "social-moral" reasoning accepts Kolberg's (1984) idea of individuals progressing from more egocentric attributions to forms of reasoning becoming more complex and abstract over time, but places a greater emphasis on the role of social perspective-taking and empathy. What seems particularly fruitful to our goal, is Gibbs's (1993, 1995, 2003) examination of the association between the process of moral reasoning, the content of social cognition, and general cognitive development, specifically those types of cognitive distortions that may contribute to the persistence of immature moral reasoning beyond childhood.

The first and primary cognitive distortion, typical of young children, is the egocentric bias, whereby attitudes and values place the individuals' own concerns as central. Moral reasoning at the lower stages (i.e., immature reasoning) is underpinned by an egocentric bias, with limited social perspective taking and an emphasis on one's own needs and desires ahead of those of other people. A range of secondary distortions supports the egocentric bias (Gibbs, 1993, 2003) and weakens inhibitions to participate in bullying. Among them are relevant *assuming the worst*, or holding a hostile attributional bias (i.e., the tendency to interpret ambiguous events as being hostile), *blaming others* for their own actions, *mislabeling of one's behavior* and *minimization of consequences* to minimize feelings of guilt and regret.

The persistence of a pronounced egocentric bias and the inability to take other people's perspective beyond childhood, along with the accompanying moral developmental delay, can lead to a greater likelihood of aggressive and harmful behavior toward others (Gibbs, 1993). Different studies have confirmed among antisocial and aggressive youths the presence of serving cognitive distortions (e.g., Barriga & Gibbs, 1996; Liao, Barriga, & Gibbs, 1998; Palmer & Hollin, 2000; Slaby & Guerra, 1988) and of a complex belief systems that enable justification of aggression (Vorrath & Brendtro). As such, aggression can be seen to result from a delay in moral development, hypothesized as a mechanism of "disengagement of moral control" (Palmer, 2003a).

Moral Disengagement

The relationship between moral disengagement and aggressive behavior, which is mediated by a reduction of feelings of guilty, pro-social behavior and cognitive evaluations has already been investigated by some researchers (Bandura, et al., 1996) especially among adolescents. Specifically, Menesini, Fonzi and Vannucci (1999) examined the disengagement of moral control in association with different participating roles in bullying (bully, victims and control) and found that bullying boys (age 6 to 14) were more prone to use dehumanization toward victims, compared to control and victim groups. An interesting study by Menesini et al. (2003) analyzed the role of moral emotions and reasoning in groups of children belonging to different participant roles in bullying (bullies, victims and outsiders) and to different cultural contexts. Children, faced with an imaginary bullying scenario, were asked to take on the bully role and were interviewed about their feelings. Moral emotions such as *guilt* and *shame*, (considered as indexes of moral responsibility), and those such as *indifference* and *pride*, (considered as attitude of moral disengagement), were investigated across the three participant roles. Bullies, compared to victims and outsiders, showed significant higher level of disengagement emotions, and showed egocentric reasoning. The study also reported cross-cultural differences attributable to a widespread culture where organized crime is almost accepted as a normal event and can easily support mechanisms of moral disengagement in young children (Menesini et al. 2003). Their results highlighted the link between socio-cultural context and individual moral reasoning and values; moreover, they evidenced how individual moral reasoning and moral emotions may be flexible and may account for different and varied aspect of the social world in which individuals are embedded. Heterogeneity and variability in social judgments and behaviors pertain to given cultures and to different individual members of that culture.

Cultural Values

Values are generally defined as principles, critical and important normative assumptions that underlie morality for individuals in relationships with others (Kurtines & Gewirtz, 1995). They are the affective component of morality and represent the implicitly or explicitly shared abstract ideas about what is good, right, and desirable in a society (Williams, 1970). Individual values and priorities are a product both of shared culture and of a unique personal experience and personality differences (Schwartz, 1999); they represent the guiding principles in life, which stir our emotions and allow us to create internal meaning. Shared cultural values, on the other hand, represent the way in which societal institutions (e.g., family, education, political and religious system) express their priorities, goals and their mode of operation. In other words, personal values (e.g., success, freedom, social order, and tradition) are the vocabulary of socially approved goals used to motivate action and to express and justify the chosen solution.

From the perspective of cross-cultural psychology, the social and cultural context is the key factor affecting the moral development of individuals and the kind of reasoning that individuals from different cultures bring to the moral discourse. The individual moral development refers to how one develops skills in understanding, managing and adhering to the moral expectations of his/her culture (Shweder, 1990; Stigler, Shweder & Herdt, 1990). Cross-cultural studies have indicated the importance of culture in determining moral reasoning

(Mizuno, 1999; Iwasa, 1992; Miller, 1988) and showed the existence of cultural variability in justice morality (Keller, et al., 1998; Edwards, 1994; Harkness, Edwards & Super, 1981; Miller et al. 1990). In the attempt to set the ground for a socio-cultural theory of altruism and aggression, Staub (1994) argued that: "In order to understand how altruism or aggression comes about, we must consider both how people select the aims of their behavior from a multiplicity of aims, and what determines whether they actually pursue the aims they selected... (p. 139)". Some researchers (Robarchek & Robarchek, 1998; Fry, 1998, Howell & Willis, 1989) have speculated that observed differences in aggression may be attributable to disparities in world views, values and belief systems. Both violent and peaceful social interactions could be understood through the sensitive and detailed explication of the values and meanings that embody and shape the behavior in different social settings (Howell & Willis, 1989). Altruistic and aggressive behaviors are multi-determined by individual characteristics, different influences and circumstances which usually join in (Staub, 1994). In studying aggression, researchers have often neglected to acknowledge the crucial relation between culture and moral reasoning. Consequently, the scientific literature on the extent to which the relationship between personal characteristic such as value orientations influences either pro-social or aggressive behavior is limited. Cross-national variability in social behaviors, including aggression and bullying, has often been attributed *post hoc* to "culture", without a clear theoretical framework and operationalization. Many authors have tried to replace "culture" with more specific, explanatory, variables (Hofstede, 1980; Schwartz, 1990). Hofstede (1980) classified culture along four dimensions: 1) Individualism vs Collectivism, which describes the emphasis placed on individual needs, ambition and success versus the well-being of the group, 2) Power Distance, which refers to the degree of difformity according to which societies accept the unequal distribution of power in institutions and organizations, 3) Uncertainty Avoidance, which refers to the extent to which rules, norms and rituals that provide stability and predictability are valued, and 4) Masculinity vs Femininity, which identifies the set of "masculine" goals, such as success, assertiveness, heroism and advancement, *versus* the "feminine" ones, focused on interpersonal relationships, modesty, nurturance and interpersonal harmony (Hofstede, 1980). Building on Hofstede's work (1980), Schwartz (1994) has proposed the dimensions of *Conservatism* (family security, social order, obedience, respect for tradition) *versus Intellectual and Affective Autonomy* (creativity, broad-mindedness, varied life, pleasure) and *Hierarchy and Mastery* (social power, ambition, wealth) *versus Egalitarian commitment and Harmony* (social justice, equality, unity with nature). Bond (1991) introduced an additional set of values derived from Chinese culture (*Integration, Human-Heartedness, Moral Discipline and Confucian Work dynamism*) in order to avoid the Western culture bias, which further confirmed the robustness of the dimensions cross-culturally.

Recent research has started using the cultural values (e.g., individualism and collectivism) at the national level to explain differences in peer aggression (Bergeron and Schneider, 2005; Forbes et al., 2009). According to Bergeron and Schneider (2005) cross-national differences in aggression could be predicted from values differences at the national cultural-level. Cultures wherein a high value is placed on individual needs and desires, getting ahead and promoting one's own interest regardless of those of others, would be more accepting of aggressive behavior than cultures in which an emphasis is placed on group goals, taking care of the collectivity, and fitting in harmoniously with the environment. Bergeron and Schneider (ibid.) reported that each of the three national values classification systems proposed by Hofstede (1980, 1983), Bond (1991) and Schwartz (1994) was found to predict differences in aggression.

Aggression scores were positively related to *Individualistic* values and negatively to *Collectivistic* values. Contrary to the expectations, Schwartz's dimension of *Affective-Autonomy* was not associated to aggression, and *Intellectual-Autonomy* was negatively related to level of aggression. Aggression scores were higher, on the contrary, in cultures where *Mastery* was a high value priority. These results taken together suggest that a generic orientation for individualism, as valued in some societies, may be not directly associated with higher level of aggression, "but rather the need to master and control the environment and the importance of getting ahead through self-assertion are linked to aggression" (ibid, p. 131). The research on cultural value orientation may explain how culture may influence the general attitude toward aggression, but a further level of analysis calls for the investigation of intracultural variations of cultural values, which may contribute to our understanding of explaining factors for individual differences in aggression within a particular culture. Multiple cultural values (e.g., individualism and collectivism) in fact, may coexist within societies and can be simultaneously endorsed by individuals as well as different culturally heterogeneous groups may be present in the same nation (Li et al., 2010).

Aims

In this study we aimed at investigating how individual life values varies in subgroup of students who are differently involved into covert and over bullying.

Based on the forgoing review of the literature and key concepts, we hypothesized that adolescents' endorsement of egalitarian orientation would be negatively related to their overt and relational aggression; conversely, adolescents' endorsement of individualism would be positively related to these aggression outcomes.

Methodology

Sample

Our sample of 801 middle school students (43.8% males, $n = 351$ and 54.3% females, $n = 435$, 15 missing; age range 10-15, $M = 12$, $SD = 1.54$) was recruited at two different schools with no specific bullying prevention program nor clear anti/bullying policies. The participating schools were selected from residential neighborhoods with a low rate of immigration and were located in the Italian region of Tuscany and Emilia Romagna. Students belonged to intact middle socio-economic families where the majority of fathers held a high school degree (22.3%) or a college degree (18.4%) with significant gender differences (for mothers 24.7%, 19.9% respectively).

Instruments

An anonymous self-report bullying questionnaire (Darbo, Buccoliero & Costantini, 2003) was administered to students by trained researchers during regular school hours, after parents' consent. Participation was voluntary, after parental written consent, with no reward nor incentive. Questions intended to assess the incidence of bullying in middle school, its type, students participating roles, where it occurs, adults' response and students' attitudes toward it. Below we give a more detailed description of the sections that will be considered in this study.

Peer Relationships at School And Perceived Attitude Toward Bullying

A questionnaire's section investigated the quality of peer relationship at school, wherein students were asked to evaluate the quality of their relationships with classmates and schoolmates on a 5 point Likert scale (from "very bad" to "good"), to report which moment of the school day they preferred to share with them (5 mutually exclusive items) and whether they were ever left alone by them (5 mutually exclusive items). In order to assess the presence of a peer attitude toward bullying in the school we also asked students to report their perception of their schoolmates' general reactions to bullying episodes, choosing two possible answers among 6 items devised to evidence a pro-bully perceived attitude or a pro-victim perceived attitude. Moreover, they were asked about their willingness to disclose what generally happens in school to classmates or friends outside.

Relationship with Adults in and Outside School

In order to evaluate students' relationship with adults we asked students to report the quality of their relationships with teachers in school (on a four point Likert scale from "very bad" to "good") and to report adults' general reaction to bullying in school, choosing only one answer among 5 possible items (yes or no response) (*"Adults in my school are not aware of what happens"; "they pretend nothing is happening"; "they're not present when it happens"; "they intervene to help who is victimized"; "they laugh and they have fun of us"*).

Moreover students were asked how much they were satisfied about their parents involvements in the school life, choosing their responses on a four-point Likert scale (from "not at all satisfied" to "very satisfied").

Life Values

The Life Values Questionnaire was composed of 12 items pertaining to life values, placed on a three point Likert scale (from "not important/very little important" to "very important"), in order to explore at the intra-individual level the three main culturally based value classification systems suggested by the work of Hofstede, Schwartz and Bond (see previous section).

The Life Values Questionnaire asked students to evaluate how important were for their life values such as Honesty, Order and respect of rules, Respect of others, Equity of possibilities for everybody, Freedom of thought, Solidarity, Justice, Tolerance for opinions and behaviors different from their own, Success, Wealth (Richness), Freedom to do what one wants, Self-realization.

Life Values Questionnaire yielded a good reliability of .86 Alpha, and the 12 items were further classified into three factors by a Confirmative Factor Analysis (see below), in order to obtain individual measures of life values orientation.

Analysis

First, we present descriptive results for all variables of interest, grouped in relationship with peers at school, relationship with adults in and out school, bullying, participating roles (bystanders, bullies and victims) and life values. Second, we describe our value classification

system obtained by factor analysis on the 12 life values. Finally, we discuss the results of multivariate analysis examining gender differences and the relationship between bullying participating roles, life values and culturally based value classification systems.

Relationship with Peers at School

Descriptive analysis showed a positive relationship with classmates, ($M=4.39$, $SD=.82$, range 1-5) and schoolmates ($M=3.94$, $SD=.89$, range 1-5). No significant differences were reported by gender.

However, more than half of our sample (51.9%, $n=416$) spent no time with class peers if not during *Class time* (28.8%, $n=226$), confirmed by only a small percentage sharing their *free time* (10.6%, $n=85$) with classmates outside school walls. Similarly, few students reported (18.8%, $n=88$) being left alone during school time by schoolmates either at recess (10.6%), during class time (3.7%), on the way to and from school (3.2%), or always (1.7%), while the majority was spending time together with classmates (79.2%, $n=634$).

Concerning the perceived attitude of their schoolmates toward bullying, a multiple response set was created including the six dichotomous items; the percentages among the total number of responses were analyzed. Students responses showed a tendency to do nothing when seeing bullying episodes (28%), or showing pro-bullies attitudes (25.9%, isolating the victim from the group and supporting actively the bully), while 33.6% of the responses reported answers which were pro-victim oriented (i.e isolating the bully from the group and giving help to the victim); a 13.1% reported to be scared from seeing the bullying episodes.

Results also showed that students felt comfortable in disclosing and discussing school matters within the school (84%, $n=673$), mostly with a trusted friend at school (59.4%, $n=476$) or with their classmates (38.8%, $n=311$).

Relationship with Adults in and Outside School

To evaluate students' perception of the quality of relationship with significant adults (teachers and parents) an Anova was run (satisfaction by Gender) among the responses to the four point Likert scale pertaining students' relationship with teachers. Results showed quite a positive relationship with teachers at school ($M=3.07$, $SD=.77$, range 1-4) with higher values for females than for males (Males $M=2.99$; Females $M=3.13$, $F=6.36$, 1 df; $p<.01$).

To assess the presence of supporting adults at school, we asked students to report adults' general reaction to bullying in school. Students reported that 47.3% ($n=379$) of adults involved in a bullying episode did actively intervene in defense of the victim while 30.3% ($n=243$) stated that adults were not present at the time of the incident and 10.7% reported adults to be either inattentive ($n=87$) or pretending nothing was happening (8%, $n=64$). A small percentage (1.2%) reported that adults in school were laughing when they witnessed Students in our sample seemed open to disclose within school walls (YES responses 84%, $n=673$); a multiple response analysis on the 5 items concerning whom they were talking to about school issues showed that students relied, as expected for adolescents, on the peer support system (50.3 % relied on a trusted peer, a 33% on classmates), but they were very reluctant in disclosing and discussing school matters with a trusted teacher (8.6%), teachers in general (5.6%) or school personnel (2.2%). Similarly, outside the school, students were less likely to disclose school matters with adults, neither their parents (32.6%) nor any other relative (12.5%) or adult figure in their lives (3.2%), while trusted friends were the reference persons (51.8%).

For what concerns parents' involvements in the school life, an Anova analysis was run by Gender on the scores of the 4-point Likert scale (from "1=not at all satisfied" to 4="very satisfied"), measuring the students' satisfaction of parental involvement. Beside a quite positive evaluation (, $M=3.41$, $SD=1.32$, range 1-4), no significant differences between genders emerged. Moreover, we asked students to what extent their parents were able to understand their feelings on a 4-point Likert scale (from "not at all" to "very much"). The majority of them reported having a quite emphatic and emotional connected relationship with their parents ($M=3.02$, $SD=1.70$), with no significant differences between genders.

Bullying at School

To assess the prevalence of the bullying phenomenon we asked students to report the presence of bullies in their school, their type (group or individual) and gender. Moreover, we asked what type of aggression they were actually perpetrating, where it was usually taking place and if they were somehow personally involved (as bystander, bully or victim). Results evidences a pervasiveness of school bullying ("*According to you, does someone in your school behaves as a bully?*": YES 75.9%, $n=608$). A multiple response tabulation on the total of responses to the categories of bullying (more than one choice on a 10 items scale) shows that bullying is characterized by teasing (23.1%), offensive language (20%), malicious jokes (12.9%), physical aggression (11.8%), threats (10.5%), group exclusion (7.8% $n=206$), stealing (minor 7.6% and major 4.5%) and extortion (1.4%).

A Chi Square analysis was performed on bullying type by Gender, showing females to report more indirect and relational bullying (*teasing*: Pearson Chi Sq. 4.02, 1 df., $p<.04$; *group exclusion*: Pearson Chi Sq. 8.77, 1 df., $p<.003$) while males were more sensitive to physical and verbal aggression (*Physical aggression*: Pearson Chi Sq. 3.75, 1 df., $p<.05$; *stealing*: Pearson Chi Sq. 4.82, 1 df., $p<.02$; *threats*: Pearson Chi Sq. 31.33, 1 df., $p<.000$).

Bullying was reported to be perpetrated more often by a group (60%, $n=481$) of males (75.3%, $n=603$) or mixed (19.6%, $n=157$), and much less frequently by one individual alone (22.2%, $n=178$) or two (14.4%, $n=115$) or by females (1.3%, $n=12$). Predominantly bullying took place on school premises, like the corridor (38%, $n=304$) and the classroom (37.1%, $n=297$). More rarely, bullying was reported to occur in *bathrooms* (14.7%, $n=118$), *on the way from and to school* (14.4%, $n=114$), or *courtyard* (9.1%, $n=73$).

In terms of direct and personal involvements, in a multiple choice question, students identified themselves as Bystander (84.5%, $n=671$), Victim (40.8%, $n=327$) and Bully (6.3%, $n=50$). Data clearly evidenced an overlap between roles indicating the majority of students as witnesses or victims. Recoding bullying participating roles into three mutually exclusive variables we obtained a very high percentage of uninvolved (neutral) bystanders (56.8% $n=455$), followed by victims (37.1% $n=297$) and bully | bully-victims (6.1% $n=49$). A Chi Square analysis showed that males are more represented in the bully/bully-victims group (4.1% of males vs 1.9% of females) and in the victim group (19% vs 18.3%), compared to females who are mostly neutral bystanders (females 35.1% vs 21.6% males) (Pearson Chi Square 22.70, $p<.000$).

Life Values

All 12 life values items proposed were evaluated by participants on a 3-point Likert scale ("not important", "important" and "very important"). Results indicated that in the whole sample, for all variables but *success* ($M=1.76$, $SD=.83$) and *wealth* ($M=1.59$, $SD=.79$), the

mean values were above 2.5, indicating they were considered quite important with *respect* ranking as the most important ($M=2.62$, $SD=.78$) followed by *freedom* ($M=2.60$, $SD=.77$) and *honesty* ($M=2.56$, $SD=.78$). A one way ANOVA within subjects was run to compare males and female life values responses. Gender difference were significant for 7 over 12 values.

Table 1. Life Values Items by Gender, Anova

	Sex	N	Mean	Std. Dev.	D.f	F	Sig.
Success	Males	351	1,91	,868	1	19,843	,000
	Females	434	1,65	,743			
Freedom of doing what one wants	Males	351	2,16	,892	1	2,642	,104
	Females	435	2,26	,804			
Justice	Males	351	2,46	,867	1	,292	,589
	Females	435	2,49	,824			
Solidarity	Males	351	2,18	,896	1	3,155	,076
	Females	435	2,29	,879			
Order and respect of rules	Males	351	2,23	,878	1	5,782	,016
	Females	435	2,37	,726			
Equality	Males	351	2,32	,927	1	13,534	,000
	Females	435	2,54	,750			
Tolerance	Males	351	1,97	,886	1	12,251	,000
	Females	435	2,18	,833			
Self-realization	Males	351	2,25	,860	1	3,451	,064
	Females	435	2,35	,782			
Freedom of thought	Males	351	2,55	,830	1	3,435	,064
	Females	435	2,65	,694			
Honesty	Males	351	2,46	,860	1	11,554	,001
	Females	435	2,65	,708			
Wealth	Males	351	1,69	,858	1	8,913	,003
	Females	435	1,52	,732			
Respect of others	Males	351	2,55	,843	1	5,939	,015
	Females	435	2,69	,712			

Females scored higher on values as *Order and Respect of Rules*, (Female $M=2.37$; Males $M=2.23$, 1 df, $F=5.78$, $p<.01$), *Equality* (Female $M=2.54$; Males $M=2.32$, 1 df, $F=13.53$, $p<.000$), *Tolerance* (Female $M=2.18$; Male $M=1.97$; 1 df, $F=12.25$, $p<.000$), *Honesty* (Female $M=2.65$; Male $M=2.46$; 1 df, $F=11.55$, $p<.001$) and *Respect of others* (Female $M=2.69$; Male $M=2.55$; 1 df, $F=5.93$, $p<.015$). Males score significantly higher than females on values such as *Wealth* (Male $M=1.69$, Female $M=1.52$, 1 df, $F=8.91$, $p<.003$) and *Success* (Male $M=1.91$, Female $M=1.65$, 1 df, $F=19.84$, $p<.000$) (see tab. 1).

Factor Analysis for Value Classification Systems

Moreover, a Principal Component Analysis was run, entering as variables the 12 value items: *Success*, *Honesty*, *Order and Respect of Rules*, *Respect of Others*, *Equity*, *Freedom of Thought*, *Solidarity*, *Justice*, *Tolerance*, *Freedom to do what one wants*, *Wealth*, *Self-*

realization. Three components were extracted with Varimax Rotation, which explained 63% of the variance. The first component was named “*Conservativism Orientation*”, as it was saturated by the values: Honesty, Order and respect of Rules, Respect of Others, Equality, Freedom of Thought; this component explained the 43% of variance (EigenValue 5.06); the second component was called “*Egalitarian Orientation*” and included the values of Solidarity, Justice and Tolerance; this second component explained the 13.11% of variance (Eigen Value 1.57). The third component was named “*Individualistic orientation*”, and was composed by values as Success, Wealth, Freedom to do what one’s want, Self-realization (see tab. 2). It explained the 6.8% of variance (Eigen Value .82). The standardized factor scores for each component were used for further analysis.

Table 2. Principal Component Analysis on Life Values

	Life Values Orientations Components		
	Conservativism	Egalitarian	Individualistic
	Eigen Value 5.06 (42.21%)	Eigen Value 1.57 (13.11%)	Eigen Value 0.82 (6.8%)
Success	,054	,049	,780
Freedom of doing what one wants	-,025	,538	,549
Justice	,351	,701	,196
Solidarity	,264	,714	-,001
Order and Respect of Rules	,791	,166	,037
Equality	,625	,453	,011
Tolerance	,373	,650	,056
Self-realization	,321	,401	,511
Freedom of thought	,600	,432	,338
Honesty	,823	,184	,130
Wealth	,087	-,014	,779
Respect of others	,763	,297	,090

Extraction Method: Principal Component Analysis.; Varimax Rotation with Kaiser Normalization.

T-Test for Gender Differences

An independent T-test Gender by standardized Factor scores on the three Value Orientations (*Conservativism*, *Egalitarian*, *Individualistic*) evidenced significant gender differences: boys scored significantly lower on *Conservativism* and *Egalitarian* orientation, but significantly higher than girls on *Individualistic* orientation (*Conservativism*: Males $M = -.11$; $F = .09$; Student $t = -2.94$, $p < .003$; *Egalitarian*: Males $M = -.11$, $F = .11$; Student $t = -3.16$, $p < .002$; *Individualistic*: Males $M = .15$, $F = -.11$; Student $t = -2.94$, $p < .000$). Italian adolescent girls seem to rely more on the “feminine” extreme of this dimension, giving more importance to interpersonal relationship, harmony and nurturance (see tab. 3) than boys do.

Table 3. Value orientations by gender

	<i>Gender</i>	<i>n</i>	<i>M</i>	<i>SD</i>	<i>T</i>	<i>df</i>	Sig. (2-tailed)
Conservatism Orientation	M	351	-.11	1.08	-2.94	783	.003
	F	434	.09	.90			
Egalitarian Orientation	M	351	-.11	.95	-3.16	783	.002
	F	434	.11	1.01			
Individualistic Orientation	M	351	.15	1.10	-3.71	783	.000
	F	434	-.11	.88			

ANOVA for bullying roles x Value Orientation

We further explored how value orientation and aggression could be linked by running Anova analysis for each component by the three participant roles, recoded as “neutral and bystanders”(NE); “bullies and bully-victims” (BBV) and “victims” (V). We found significant differences among the role-groups across all the three components (Conservatism $F_{12.99}$, $p=.00$; Egalitarian $F_{3.08}$, $p=.046$; Individualistic $F_{6.54}$, $p=.001$, $d.f.=2$). (see tab.4)

Table 4. Value orientations by Bullying participant roles Anova.

Value orientation	Roles	n	M	SD	Min	Max.	F	Sig.
Conservatism Orientation	Bystander	454	.085	.89	-3.03	1.61	12.99 (2 df)	.000
	Bully or Bully-Victim	49	-.66	1.21	-3.03	1.48		
	Victims	297	-.02	1.07	-3.99	1.76		
	Total	800	.00	1.00	-3.99	1.76		
Egalitarian Orientation	Bystander	454	.06	.95	-2.76	2.15	3.08 (2 df)	.046
	Bully or Bully-Victim	49	-.23	1.13	-2.25	1.98		
	Victims	297	-.06	1.04	-3.01	2.00		
	Total	800	.00	1.00	-3.01	2.15		
Individualistic Orientation	Bystander	454	.00	.93	-2.89	2.45	6.63 (2 df)	.001
	Bully or Bully-Victim	49	.46	1.23	-2.32	2.66		
	Victims	297	-.08	1.03	-2.86	2.33		
	Total	800	.00	1.00	-2.89	2.66		

The post-hoc analysis (LSD) revealed the Bully and Bully-Victim profile (BBV) to be significantly different from other roles on all the values components: Bullies and Bully-Victims scored lower than Bystanders and Victims on *Conservatism* and lower for *Egalitarian* orientation compared to bystander subjects only; on the contrary, Bullies and Bully-Victims scored higher on *Individualistic* orientation compared to bystanders and to Victims; (see Table 3).

ANOVA for Gender x Value Orientation X Bullying Roles

Finally, running an ANOVA on *Conservativism* by Sex and by Roles we tested whether the reported differences among values orientations were due to gender distribution in the bullies-and bully-victims group (BBV). No gender effect was found while the interaction Role by Sex was significant. The difference was due to BBV females that scored lower than BBV males on *Conservativism* (BBV Females $M = -.91$; BBV Males $M = -.43$). The *Egalitarian orientation*, when entered into the Anova analysis with Roles and Sex, was significant only for the general effect, but not for the separate variables nor their interaction (Egalitarian Orientation by Sex By Roles, 5 d.f., $F 3.56$, $p = .003$; Sex (1 d.f.) $F 1.53$, n.s.; Role (2 d.f.) 1.78 , n.s.; Sex by Role (2 d.f.) $F 1.89$, n.s.). The comparison among means showed that males NE (Bystanders) scored lower than females NE, but no differences due to gender were found for bully-victims group (BBV) and Victims (V). The *Individualistic* orientation confirmed what we examined above (Individualistic by Sex by Role, (5 d.f.), $F 6.78$, $p = .000$; Sex (1 d.f.) $F .063$, p.n.s.; Role (2 d.f.) $F 8.69$, $p = .000$; Sex by Role $F 3.53$, $p = .030$) with males scoring higher than females, and significant differences for Gender, Role and their interaction (Gender by Role). BBV were significantly higher than NE and V, but surprisingly BBV females reported higher means than BBV males. This seems to suggest that girls who are involved in active bullying have an individualistic orientation which encompasses the cultural "milieu".

CONCLUSION

Bullying is a social interaction that requires complex relationship solutions at the peer and adult level. Classmate friends and peers who do intervene in bullying make a real difference (Farrington & Ttofi, 2009) as peer relationships are crucial both for the bully who looks to maintain or acquire social status and for the child who looks to cope with and end victimization. Classroom and school climate, school organizational environments and social infrastructure can send a message to all students that bullying conflicts with the basic values of respect and tolerance. Adults are also responsible for ensuring that disclosing bullying, inside and outside school, will lead to a positive outcome and for providing extensive, dynamic, and ongoing support to youth. They can redirect bullies' leadership potential from the negative strategies of peer aggression to positive leadership skills and opportunities by teaching them how to relate to others positively, be effective in achieving social goals, and use power in a positive manner. Social skills clearly play an important role in bullying. In our study, bullies belong to two coexisting social worlds: *marginalization* and *connection* (Farmer et al., 2010). Socially marginalized, unpopular bullies fight against a social system that keeps them on the periphery and lack peer social support, whereas socially connected bullies are socially skilled and competent, peer networked and integrated. Socially connected bullies tend to be proactive and goal-directed in their aggression (Card & Hodges, 2008) and they target children who are likely not be defended (Veenstra et al., 2010). Socially marginalized, rejected-aggressive bullies who often are also victims, predominantly act aggressively, impulsively, in reaction to provocation, or in the attempt to gain status that generally eludes them (Pellegrini et al., 2010). In our study, proactive bullies were mostly represented.

They seem to belong to that group of socially competent subjects, using their skills to their advantage, but seem to lack the empathy to integrate such information into their interactions.

This manipulation of social relationships requires verbal, cognitive and social skills (Crick & Dodge, 1999) and the ability to identify successfully the social and emotional weaknesses of the targeted victims (Arsenio & Lemerise, 2001). This form of social aggression “may lie in the values of the bully rather than in the accuracy of the cognition (Sutton, Smith, P. K., & Swettenham, 1999, p. 122). The empathic styles, moral and cultural values and emotions of bullies and victims may substantially differ. We have explored in our study the normative area (i.e., moral values, norms, standards, and beliefs) as we consider it also important to in attempts to explain the moral side of bullying. Shared cultural values, in fact, are the basis for specific norms that tell people what is appropriate in various situations within a society and help shaping the contingencies to which people must adapt in the institutions in which they spend their time. They represent the way in which societal institutions (e.g., family, education, political and religious system function) express their priorities, goals and their mode of operation. Our study primary supports the claim that proactive bullying is associated with an individualistic and instrumental orientation: personal success and richness drive bullies, while more social and altruistic values characterizes victims and neutral bystanders. This pattern remains stable, despite the gender influence: female bullies, in fact, report having higher scores on Individualistic orientation, contrary to the cultural expectations, which sees females as more prone to socially oriented values. These results highlight the importance of considering the dimensions of moral orientation and life values in the bullying process.

Our results also confirmed gender differences in moral values, which could as well be attributed to specific cultural orientations and norms. Gender differences were significant, with females indicating more social and altruistic values than males, preferring success and personal achievement. Italy, according to Hofstede (1980), ranked among the countries with the highest scores in the dimension of “Masculinity”, corresponding to the value placed on material success, assertiveness, heroism and advancement. This probably could be attributed to a widespread *familialism* (the male breadwinner being the primarily responsible for the wellbeing of all family members) of Italian national culture (Giancesini, 2013). Especially in Italy, where the subsidiary principle and its familistic policies are central, conservative gender-specific division of labor within the family exists and female employment depend on care responsibilities rather than job opportunities and individual qualifications.

Our research, questionnaire-based, differs from other studies on moral reasoning where the primary emphasis was on response evaluation as we broadened the view of moral orientation by including “life values”, which are culturally influenced. Some issues need to be addressed here.

The ideological orientations of societies shape the form of moral justifications, sanction detrimental practices and greatly influence who is casted into devalued groups. Cultural and social-structural practices create conditions, which could be conducive to moral disengagement and favor its disinhibitory power. Some of the moral disengagement practices, such as diffusion and displacement of responsibility, are built into the organizational and authority structures of societal systems, and this is especially true for Italy (Giancesini, 2013). A pyramidal hierarchy and an impersonal bureaucracy but with great individualism characterize Italian society (Hofstede, 1980) where the displacement of responsibility derives from very early stage of socialization, which establishes the diffusion of the everybody’s and nobody’s responsibility notion. It is also true, however, that people are both producers as well as products of social systems. Within a society, individuals may have somewhat a different set of subjective values and, more or less, adapt to the prevailing cultural ideology or have a different subjective

interpretation of it. In order to explain the link between cultural values and aggression, is therefore particularly relevant to account for subjective culture and individual measures of cultural variability. Further analyses is needed to improve the measures for individual life values and to explore more in detail the link between moral, social and cultural domains. Different levels of analyses and multiple longitudinal data are necessary to fully understand the interaction of these variables and address bullying in a “comprehensive treatment package”. To prevent or contrast the bullying phenomenon, issues related to families and parenting style, social information processing, cognitive distortions, emotion regulation and moral reasoning altogether must be properly addressed, including the affective and motivational side of aggression, to help individuals develop more socially appropriate and competent ways of pursuing their goals in the social context.

Chapter 58

BULLYING AS AN ORGANIZATIONAL SAFETY ISSUE: DO DIFFERENT TYPES OF BULLYING LEAD TO DIFFERENT LITIGATED OUTCOMES?

Helen LaVan, Yvette P. Lopez and Wm. Marty Martin

DePaul University, Chicago, IL

ABSTRACT

Workplace bullying is widespread. A recent meta-analysis found that the prevalence rate across 86 independent samples was 14.6% (Nielsen et al., 2010). Bullying occurs often enough for the International Labor Organization (ILO) to emphasize physical and emotional violence as being one of the most serious problems facing the workplace in the new millennium (Canadian Safety Council, 2004). Congress enacted OSHA in 1970 with the stated purpose “to assure safe and healthful working conditions for working men and women.” It is argued in this chapter that workplace bullying poses a threat to safe and healthful working conditions. This workplace safety and health threat is associated with different legal outcomes depending upon whether the victim of bullying files a cause of action based on formal or informal bullying behaviors in the court system in the United States.

LITERATURE REVIEW

Bullying in the workplace has been investigated from a variety of perspectives ranging from the legality of workplace bullying (Yamada, 2005) to the ethics of workplace bullying (LaVan and Martin, 2008). This chapter will examine workplace bullying as an issue of organizational safety. Other researchers have viewed workplace bullying as an organizational safety and health issue (Jenkins et al., 2011) and a public health issue (Lovell and Lee, 2011). Furthermore, Lovell and Lee (2011) regard workplace bullying as an occupational safety hazard. To take an organizational safety perspective of workplace bullying requires that the legal context of bullying be discussed as well as the formal and informal behaviors that constitute workplace bullying. Furthermore, given the legal context of viewing workplace

bullying as an organizational safety issue, the outcomes for victims of workplace bullying will also be focused upon in this chapter with particular attention to the litigated outcomes.

Workplace Bullying: A Definition

There are numerous definitions of workplace bullying. In this chapter, workplace bullying is defined as consisting of three qualities: (1) the regularity of bullying over a six-month period; (2) the victim experiences challenges defending himself or herself; and (3) a difference in power between the victim and the bully. This definition is based upon the work of previous researchers (Lindstrom et al., 2000; Law et al., 2011).

Prevalence of Workplace Bullying

The prevalence of workplace bullying is in part related to the definition of workplace bullying. In one of the more rigorous prevalence studies of workplace bullying, it was estimated that 47 million U.S. workers are victims of workplace bullying in any given year, which is equivalent to 41% of the working population in the United States (Schat et al., 2006). In a polling study conducted by The Workplace Bullying Institute (2007), the lifetime prevalence was estimated to be 37% of the working population or 54 million Americans. The precise number and prevalence whether point prevalence, annual prevalence or lifetime prevalence is debatable but the number of workers exposed to workplace bullying and the number of witnesses exposed to workplace bullying as well as the number of individuals accused of workplace bullying add up to millions in any given year. This is why workplace bullying is considered not only an occupational safety and health issue but also a public health and social issue.

Workplace Bullying as an Ethical Issue

Although beyond the scope of this chapter, some have asserted that there is a strong relationship between local ethical climates and workplace safety (Parboteeah and Kapp, 2007). According to Schneider (1990), an ethical climate is the “incumbents’ perceptions of the events, practices and procedures and the kinds of behaviors that get rewarded, supported and expected in a setting (page 384).” Hence, the manifestation of workplace bullying behaviors occurs within the context of the ethical climate of a particular organization. Law et al. (2011) refer to such an ethical climate as a psychosocial safety climate and discuss this climate from the point of view of both bullying and harassment.

It has further been argued that ethical climates “serve as a modifier of motive and opportunity, either prompting or discouraging organizations from engaging in illegal behavior (McKendall et al., 2002, page 367).” The apropos law regarding workplace bullying is the Occupational Safety and Health Act (29 U.S.C. § 651 et seq.).

Legal Context

Even though workplace bullying is not illegal in the United States, victims of workplace bullying have prevailed in the court system by using other laws and legal theories to restore justice (Martin and LaVan, 2009; Martin, Lopez, and LaVan, 2010). Harthill (2009) references other laws that can be used by victims of workplace bullying ranging from Title VII hostile work environment protection to intentional infliction of emotional distress.

Beyond using other laws and legal theories, commentators have concluded that OHSA could "... be utilized and/or strengthened to incorporate coverage of bullying as a recognized workplace safety and health hazard... (Harthill, 2009)." The OHSA general duty clause is broad enough to cover acts of workplace bullying because it requires employers to maintain safe working conditions. Section 5 of the OSH Act sets forth a covered employer's duties. The first clause, section 5(a)(1) is called OSHA's "general duty clause" and provides that each employer must furnish its employees with a workplace "free from recognized hazards that are causing or are likely to cause death or serious physical harm." According to Namie and Namie (2004), workplace bullying falls more so under the category of psychological violence but violence nevertheless. As such, any violence occurring at work falls under the purview of OHSA.

The National Institute for Occupational Safety and Health (NIOSH) regards workplace bullying as a subset of workplace violence (2004). Moreover, NIOSH categorizes workplace bullying as a subset of workplace violence. Balducci et al. (2011) define workplace bullying as "...a prolonged exposure to frequent hostile behaviors at work, which can lead to severe stress reactions (page 499)." Balducci et al. (2011) in a study of workplace bullying assert that workplace bullying arises from both individual factors, specifically personality, and environmental factors, specifically work environment. Hence, there is an interaction between the individual and the work environment.

Outcomes for Victims of Workplace Bullying

There is a host of outcomes for victims of workplace bullying. The two primary outcomes considered in this chapter are the health and safety effects of bullying as well as the litigated outcomes of those victims who file a cause of action in a court. First, the health effects are numerous and deleterious (Namie and Namie, 2009). Specifically, workplace bullying has been associated with psychosomatic stress symptoms, muscular-skeletal symptoms, anxiety, and depression (Hoel, Rayner, and Cooper, 1999; Kivimaki et al., 2003). Other researchers have found that perceptions of workplace injustice are linked with chronic stress, high blood pressure, and increased risk of coronary heart disease (De Vogli et al., 2007). Second, Namie and Namie (2009) argue that workplace bullying "...can be a lethal form of workplace violence (page 203)."

Although victims suffer the greatest degree of harm, witnesses coworkers are also effected (LutgenSandvik et al., 2007). Not only are victims and those who vicariously experience workplace bullying impacted but so too are those accused of workplace bullying. Specifically, it was found that those accused of workplace bullying also experience negative health consequences particularly anxiety, depression, and stress (Jenkins et al., 2011). Accordingly, a focus on workplace bullying from a point of view, which embraces occupational safety and health, must be broader than the victim.

Types of Workplace Bullying

Workplace bullying occurs at both an individual (Olweus, 1991) and group level (Einarsen et al., 2003). In addition, workplace bullying has been shown to increase after organizational changes (Skogstad et al., 2007). Ramsay et al. (2011) comment, "Workplace bullying has serious negative implications for individuals, groups, and organizations (page 802)." Bullying is not limited to a single perpetrator and single victim as demonstrated by Leymann (1996) who discovered that "...slightly more than 40% of victims subjected to attacks by two to four persons (page 175)."

In this chapter, we distinguish between formal and informal workplace bullying behaviors. Formal workplace bullying behaviors are those behaviors that occur because of managerial and organizational decisions and actions such as discrimination and unfair pay. Salin (2003) found that workplace bullies are often rewarded for bullying such as in those instances where a promotion results from the productivity effects of bullying. In contrast, informal workplace bullying behaviors are those behaviors that take place because of unsanctioned actions of employees or customers such as harassment or intimidation. With regard to harassment and intimidation, these two types of informal bullying behavior have been categorized as workplace violence (Serantes and Suarez, 2006). According to Serantes and Suarez (2006), following this line of reasoning, "workplace violence can cause health risks for the victims...page 235)."

Informal workplace bullying behavior has also been found to exist when employees are ill-treated and subject to hostile behavior (Einarsen et al., 2003; Keashly, 1998; Pearson et al., 2001). Researchers have characterized perpetrators of workplace bullying as "...domineering, vindictive, cold, socially avoidant, and distrustful (Glaso et al., 2009, page 1327)." This description fits with existing research by others (Keashly and Jagatic, 2003). Even if informal workplace bullying behaviors are not part and parcel of the formal organization, organizations and managers have a responsibility to prevent and address workplace bullying formally (Glaso et al., 2009).

Organizational Context

The way in which an employer addresses complaints of workplace bullying will result in perceptions of justice and fairness on the part of both the victim and the alleged bully. Fox and Stallworth (2005) discuss the linkage between workplace bullying and organizational justice particularly in those situations in which the supervisor is the workplace bully. The filing of workers' compensation claims has been found to be associated with perceptions of workplace injustice (Winefield et al., 2010; Roberts and Markel, 2001) and even wrongful termination suits (Lind et al., 2000).

From an organizational perspective, Lovell and Lee (2011) recommend that worksite wellness programs specifically address workplace bullying as part of mental health promotion. Liefoghe and Davey (2001) assert that top management by focusing upon the culture of the organization can both prevent and remedy workplace bullying. One of the dilemmas of addressing workplace bullying from the perspective of employers is that only 1.6% of U.S. employers believed that workplace bullying occurs frequently in their organizations (Grubb et al., 2004) according to a NIOSH-NORC survey. In short, there is a discrepancy between the perceptions of prevalence among employers and employees. This poses problems because if

organizations do not regard workplace bullying as prevalent, then the rational response, especially during times of austerity, is to fail to invest in prevention and remediation programs. Left with no organizational recourse, the rational response for some victims is to seek legal action.

METHODOLOGY

The data for this research was acquired by using BNA database of litigated cases. All usable cases for the years 2006 to 2008 were retrieved using the search strategy (bully OR bullying AND employee)¹. The timeframe of three years was selected in order to discern a relatively recent perspective on litigation relating to bullying, i.e., what is going on currently in the legal arena? This search resulted in 522 usable cases, which comprise the data.

Content analysis was done on the cases and if a particular characteristic was present, it was coded as 1 and if absent it was coded as 0.

RESULTS

Types of characteristics, as suggested by the literature, include legal context, type of bullying behavior, and case outcomes. Legal context included both legislation and possible tort actions. Legislation included constitutional amendments, federal EEO laws, federal laws-other than EEO and state laws. Important frequencies for the cases are as follows: discrimination including Title VII, the Americans with Disabilities Act, and hostile work environment were the bases of 272 of the 522 cases. This accounts for 52% of the cases. Constitutional amendments were the basis for 114 or 22% of the cases. State laws were involved in 72 or 14% of the cases. Retaliation was formally involved in 343 or 67% of the cases. Possible tort action included intentional infliction of emotional distress, defamation, privacy, and breach of contract. Thirteen of the cases involve intentional infliction of emotional distress, eight involved intimidation and 11 involved tort action in general. There were breach of contract issues in eight cases, defamation in seven cases and privacy in an additional eight cases. With respect to case outcomes, the individual prevailed in 15.9% of the cases, the case outcome was split in 22.8% of the cases and in 56.5% of the cases, the employer prevailed. Note that these percentages do not total 100% due to some missing data.

Bullying behavior was classified as formal or informal. Formal bullying types are ones that the organization can control through managerial actions, at least to some extent. Informal types, not as easy to manage, are more the result of interpersonal dynamics. Table 1 summarizes the formal and informal bullying behaviors that existed in the litigated cases that were analyzed. The most prevalent forms of bullying behavior are discrimination and retaliation, which occurred in 52% and 65.8% respectively. The next most prevalent form was unlawful termination, which occurred in 11.8% of the cases. With respect to informal behaviors,

¹ Publications based on this dataset appear in Martin, M., Lopez, Y. & LaVan, H. (2009). What legal protections do victims of bullies in the workplace have? *Journal of Workplace Rights*, 14 (2), 143-156 and Lopez, Y., LaVan, H., & Martin, W. (2010), Specific characteristics distinguishing winning from losing: Litigated workplace bullying cases. *Journal of Workplace Rights*, 15(2), 135-149.

harassment occurred in 16.8% of the cases. Table 1 categorizes the types of formal and informal behaviors involved in bullying.

Table 1. Formal and Informal Bullying Behaviors

Formal Behaviors	Frequency of occurrence
Discrimination	52.0
Retaliation	65.8
Discipline/suspension	5.7
Unfair pay	1.7
Failure to reinstate	0.2
Breach of contract	1.5
Unlawful termination	11.8
Benefits and compensation	6.5
Informal Behaviors	
Harassment	16.8
Intimidation	1.5
Interference	2.1
Defamation	1.3
Intentional infliction of emotional distress	2.5
Invasion of privacy	1.5

Table 2. Multivariate Analysis: Logistic Regression

	Formal methods	Informal methods
Overall classification – percent correctly identified	60.0 percent	61.8 percent
Accurate predictions for individual split Block 1	6.0 percent	8.5 percent
Omnibus test	Chi-square 9.594, df=5, p=.295	Chi-square 13.486, df=6, p <.05
Hosmer and Lemeshow	Chi-square 3.736, df=5, p=.588	Chi-square .732, df=2, p=.694

One research question was whether the outcome of formal or informal types of bullying behaviors could be predicted by the use of logistic regression modeling. A logistic regression analysis was performed with individual and split outcomes in one category of the dependent variable and organizational outcomes in the other category. A total of 522 cases were analyzed. See Table 2. The formal types of workplace bullying behaviors, which were entered into the first model were discrimination, retaliation, discipline/suspension, unfair pay, failure to reinstate, breach of contract, unlawful termination and benefits and compensation. The full model does not significantly predict outcomes for the individual/split (omnibus chi-square = 9.594, df = 8, p=.295). It classifies 60% of the cases. The Hosmer and Lemeshow statistic is a test of the null hypothesis. Results indicate that the model is a good model as indicated by a

high p value. This model has a p value of .588, showing that the model is a good, but not ideal, fit. The informal types of workplace bullying behaviors were entered into the second model and were harassment, intimidation, interference, defamation, intentional infliction of emotional distress and invasion of privacy. The full model significantly predicted outcomes for the individual/split (omnibus chi-square = 13.486, df = 6, $p < .05$). It accurately classifies 62% of the cases. The Hosmer and Lemeshow statistic is a test of the null hypothesis. Results indicate that the model is a good model with a high p value of .694.

This model is a better fit than the modeling of the formal types of workplace bullying behaviors. Hence, while there is only a small difference in the percentage of cases classified correctly by the formal and informal types of workplace bullying behavior, the informal types are more parsimonious.

CONCLUSION

A key finding in this chapter was that informal types of workplace bully behaviors are a more statistically significant predictor of court decisions involving workplace bullying than the formal types of workplace bullying. This fits with existing evidence regarding the interpersonal aspects of workplace bullying (Einarsen et al., 2003; Keashly, 1998; Pearson et al., 2001).

About one-half of our cases involved discrimination based upon Title VII, ADA, and other civil rights legislation. This fits with existing findings from other studies (Harthill, 2009). On the other hand, our findings are not consistent with previous research with regard to managerial responses to bullying in the form of retaliation, which is higher in our study than other studies. Moreover, harassment was not as high in our study as previous studies (Serantes and Suarez, 2006). The implications of our findings for human resources professionals, managers, and attorneys will be discussed below.

It is important for management to understand the legal consequences of bullying in the workplace. The current findings suggest that when there are more informal types for bullying, it can be predicted that the individual will prevail in litigation or at least prevail in part of his or her lawsuit. These informal types are more likely to occur in that laws prohibiting such behaviors are nonexistent.

It is precisely in these contexts of interpersonal dynamics that workers' safety becomes jeopardized. It thus becomes imperative that managers manage to control interpersonal dynamics so that individuals are not bullied. Formal methods of bullying are more explicitly prohibited by a variety of laws including EEO laws, equal pay laws, and the expectation of procedural justice.

HUMAN RESOURCES PROFESSIONALS

Given the empirical finding that informal types of workplace bullying behavior were statistically associated with litigated case outcomes, it is essential that human resources professionals enlist the knowledge and skills of not only legal and employee relations but also training, organization development and even coaches. It is within the expertise of training and development professionals that these informal workplace bullying behaviors can be prevented

and addressed. In addition, for those involving harassment and intimidation with a gender, racial, religious or other dimension of diversity, then it is critical that appropriately trained and credentialed diversity practitioners be sought for their expertise.

MANAGERS

Managers should balance their attention to the legal/regulator environment with the climate and culture of their respective departments. In fact, managers should be very sensitive to group dynamics, team dynamics, and how individual employees are treated not only by management but by other members of the team, co-workers in other functions and departments as well as treated by customers.

ATTORNEYS

Attorneys representing the plaintiff or defendant can use the findings from this investigation to best represent their client. As an attorney for the plaintiff, evidence should be collected regarding the safety climate and culture of the organization with a particular focus on harassing and intimidating behaviors, which rise to meet the standard of workplace violence. If the evidence is present, then the plaintiff's attorney may be able to use the OSHA General Duty Clause as a cornerstone to the case against the defendant, the employer and the alleged workplace bullying perpetrator. On the other hand, as an attorney for the defense, evidence should be gathered regarding how the manager and the employer offered workplace violence, bullying and anti-harassment training and education for all employees, including management, and how the employer has a policy, procedure and practice to report such instances and investigate such instances as well as appropriate language in all pertinent policies about sanctions for those who are found to have bullied others in the workplace.

In closing, workplace bullying continues to attract the attention of researchers, policy makers, and human resources professionals not to mention attorneys. Yet, the framing of workplace bullying as an legitimate occupational safety and health concern has not been fully embraced in the United States but there is mounting evidence, including this investigation, that workplace bullying should be viewed as an occupational safety and health hazard that needs to be eliminated from the workplace. Future research should continue to investigate workplace bullying using theories and constructs from then occupational safety and health literature and conduct investigations employing qualitative, quantitative and mixed methods research designs to understand fully the nature of workplace bullying with the ultimate aim to reduce or eliminate the prevalence and associated harms of workplace bullying.

ABSTRACT

School bullying has become an explicit, burgeoning problem challenging the healthy development of children and adolescents in Hong Kong. Many bullying prevention and intervention programs focus on victims and bullies, with bystanders treated as either non-existent or irrelevant. This paper asserts that bystanders actually play pivotal roles in deciding whether the bullying process and dynamics are benign or adversarial. Bystanders' own abilities and characteristics often influence how they respond to victims and bullies. "P.A.T.H.S. to Adulthood: A Jockey Club Youth Enhancement Scheme" (P.A.T.H.S. = Positive Adolescent Training through Holistic Social Programmes) is an evidence-based positive youth development program which shows that primary intervention programs have constructive impacts on junior secondary school students' beliefs and behavior. This paper asserts that intra-psychic qualities, namely identity, self-efficacy and self-determination, greatly influence how bystanders react in school bullying situations. The paper also explains how classroom-based educational programs based on the P.A.T.H.S. model have been designed to help junior secondary school students strengthen these characteristics, so that they can be constructive bystanders when they encounter school bullying.

Keywords: Bullying, bystander, positive youth development, positive identity, self-efficacy, self-determination

INTRODUCTION

School bullying is a form of aggressive behavior, characterized by deliberate, repeated, and harmful abuse of power against victims who cannot easily defend themselves [1,2]. School bullying takes different forms and is often categorized into four types: physical bullying, verbal bullying, social exclusion, and extortion [3,4]. Physical bullying refers to overt physical aggression such as slapping, pushing, kicking, and spitting. Verbal bullying, which refers to overt verbal aggression, includes name-calling, teasing, insulting and threatening speech. Social exclusion refers to damaging a target's peer relationships or social standing; and tactics can include spreading rumors, ignoring the victim's presence, threatening others not to play with the victim, or directing threatening or intimidating stares towards the victim. Extortion is asking for money or property. In recent years, advancements in information technology have made cyber bullying a new challenge because it is easy to commit but difficult to prosecute.

School bullying has detrimental effects on bullies and victims, as well as on bystanders. Such harm can range from physical, psychological to mental; from intrapersonal to interpersonal; and from short to long term [2,5,6]. Bullies are at risk of becoming increasingly short of compassion and concern for others. They eventually are desensitized to bullying, which then becomes part of their normal life [7]. They may indulge in the satisfaction of aggressive behavior instead of academic pursuits, and thus are more likely to drop out of school and be involved in gangs, delinquent activities and antisocial behaviors [2,5]. They might have increased difficulty in maintaining healthy intimate interpersonal relationships and become abusive spouses and parents [4,8]. Over the long term, they are at increased risk of depression and suicide [9].

For victims, extensive effects – persisting to adulthood – are seen on emotional, mental, psychological, physical, social and academic functioning [1,6,10,11]. Those who are bullied during childhood are more likely than non-victims to report depression, trait anxiety, and social anxiety [12], social anxiety and social phobia [13], as well as low self-esteem, loneliness and relationship dysfunction [14].

Bystanders, too, are impacted. Students who observe bullying report feeling helpless, uneasy and distressed. They often harbor guilt for not having helped the victim, anger towards themselves and the bully, and fear of becoming targets themselves [10,15]. They may also feel insecure at school and become inattentive in class as their attention is directed toward avoidance of bullying [10]. These effects can also carry over into adulthood – inability to solve problems assertively, distorted views of personal responsibility, desensitization toward anti-social acts, and diffusion of boundaries on acceptable behavior [10].

School bullying is one of the top three misbehaviors in students, with frequency and severity increasing [6,16,17]. In Hong Kong, a 2004 study on secondary-school teachers' and students' perceptions of bullying found that more than 50% of the respondents had been involved in bullying, as bullies, victims, or bystanders [17]. In a 2008 study by the same group of researchers, 87% of respondents reported witnessing verbal bullying in the past 6 months, with 30% of them having seen it more than 10 times. Also, 68% of the respondents had experienced physical bullying in the past half year, with 14% experiencing it more than 10 times [4]. This worrying trend demands immediate work on effective strategies for the amelioration and prevention of school bullying.

School bullying has attracted massive research, and there are plenty of programs for bullies and victims [18-22]. Unfortunately, even though it is obvious that school bullying typically occurs in social contexts, existing studies often assume a bully-victim (dyadic) rather than a bully-victim-bystander (triadic) perspective. Bystanders are often taken as mere “passers-by”, “observers” or “onlookers,” as if they are transparent and immobile. In fact, bystanders warrant research attention because, in the social contexts of school bullying [23,24], all people present are inevitably engaged in interactions, be they explicit or implicit. Bystanders, who witness the bullying as it develops, occurs and ends, cannot possibly be inactive in the process – whether they act or refrain, they have already added energy to either the bully or the victim. Understanding bystanders is also important because a) they typically outnumber the bullies and victims and b) they experience intra-psychic struggles, which are amenable to adjustment through psychoeducation.

In view of these traits, and of the pressing need to combat school bullying, this paper will advocate for giving due attention to the important role of bystanders in the understanding and management of school bullying. While teachers, school staff, and parent/non-parent volunteers in schools can be influential bystanders in the school bullying process, this paper confines its discussion to peer bystanders.

BYSTANDERS’ POSITION-TAKING AS STRATEGIC INTERVENTION

Peer bystanders, who are the biggest group in school bullying and who may choose to adopt a variety of roles in school bullying, can decisively influence the intensity and outcome of bullying by assuming different roles or positions in the bullying process [5,25,26]. Twemlow, Fonagy and Sacco [26] have identified several different bystander roles. *Bully* (aggressive) bystanders may sustain bullying by offering positive feedback, such as joining in or actively reinforcing through laughs or encouraging gestures. *Victim* (passive) bystanders might simply stand aside and keep silent while observing, which actually renders silent consent [24,27,28] and becomes part of the victimizing process. *Avoidant* bystanders might facilitate victimizing by denying personal responsibility. *Abdicating* bystanders might use scapegoating to shed responsibility. In contrast to these first four types, *Altruistic* bystanders might mobilize personal or social resources to help reduce or even stop bullying, e.g., defending victims, taking sides with victims, informing and seeking help from adults, comforting victims, or trying to make bullies stop [24]. In many incidents, when peer bystanders intervene against bullying, it tends to stop quickly [29].

After acknowledging the pivotal function of peer bystanders in influencing the course of school bullying, and identifying the different positions of such bystanders, it is logical to ask whether bystanders can be helped to take up the altruistic position to reduce school-bullying, and how this can be achieved. According to Twemlow, Fonagy and Sacco [26], bystanders are actually uncomfortable in non-altruistic roles, or are at least caught in the dilemma of choosing among the different roles. Therefore, they are motivated to seek effective ways out. This search (i.e., a bystander taking a position) is affected by various environmental factors. *Physical* environmental factors include classroom spaciousness and even home proximity to bullies and victims. *Social* environmental factors include the availability of parents, teachers, other adults or peers for protection or role-modeling of different attitudes and skills of coping. In addition,

the bystander's physical characteristics, social and academic status [5] and even social skills [25,30] are certainly variables that influence bystanders' position-taking.

In addition to these extra-psychic factors, the intra-psychic qualities of the individual bystander (e.g., positive self-identity, self-efficacy and self-determination) are even more important, according to psychoeducational and clinical literature on bystanders [10,29,31-33]. In a bystander's spontaneous position-taking, these intra-psychic qualities are not only directly and immediately relevant; they are also the factors most amenable to the control of the bystander.

POSITIVE IDENTITY, SELF-EFFICACY AND SELF-DETERMINATION IN BYSTANDERS' POSITION-TAKING

Positive Identity

Identity is a constellation of personality characteristics and social styles through which one defines oneself and is recognized by others. The development of a clear and positive self-identity rests on building self-esteem, facilitating the exploration of and commitment to self-definition, and reducing inconsistencies in the self to enhance role formation and achievement [34]. This definition of positive identity gives three clues to how bystanders can be constructive helpers in school bullying. The first strategy is to enhance the bystander's positive self-esteem, which is highly correlated with prosocial behavior and positive well-being [32,35]. The second strategy is to engage the bystander in thinking through and working out responses to situations like bullying, and upholding such options. Finally, the bystander needs to see the gaps between their ideal, real and perceived selves, seeking to sort out such gaps in order to achieve peace of mind. To activate such strategies, it has been effective to present the potential bystander with case scenarios for guided discussion with self-reflection on choice of responses. The evaluation findings of Project P.A.T.H.S. reveal that students participating in the program performed better than their counterparts in different areas of psychosocial competencies and strengths, including positive identity, self-efficacy and self-determination [36-38]. They also have lower intention to engage in problem behavior and higher life satisfaction [37].

The social identity of peer bystanders (i.e., at school) can also explain why genuine, high self-esteem is important in encouraging students to take the positive side in bullying. Some studies suggest that students of low self-esteem may attempt to gain social status in school through bullying others [39-41]. On the other hand, Salmivalli et al. [27] found that defenders of the victim had the highest social status, suggesting that "a child's social approval (positive status) is connected with obedience to rules, with friendliness, and with prosocial interaction" (p.3). The defenders' high social status might be gained by others' appreciation of courageous, victim-defending behavior. Genuine high self-esteem, which is positively correlated with prosocial tendencies, is therefore needed for such behavior, as defending victims puts bystanders at risk of becoming victims themselves [35].

Self-efficacy

Bandura [42] defined self-efficacy as “beliefs in one’s capabilities to organize and execute the courses of action required to produce given attainments.” Self-efficacy plays a central role in “exercise of personal agency” and revolves around the idea that “unless people believe that they can produce desired effects by their actions, they have little incentive to act” [43, p.1206]. It functions as a multilevel and multifaceted set of beliefs that can include a global self-efficacy or self-efficacy regarding different domains of the self [44]. Self-efficacy has been shown in both Hong Kong [17] and overseas [31] studies to positively affect prosocial behaviors, including bullying defending behavior. Students high in social self-efficacy are likely to try to help victims in bullying situations, whereas students with low levels of self-efficacy are more reluctant to intervene and help, regardless of their level of empathic responsiveness [45]. Even if peer bystanders know how to intervene effectively, if they believe that they will be ineffective or that other bystanders are more competent, they will be less likely to take action against bullying [25].

Self-determination

Self-determination is defined by Catalano, Berglund, Tyan, Lonczak and Hawkins as “the ability to think for oneself, and to take action consistent with that thought” [46, p.19]. It refers to the competence in thinking for oneself and autonomy in choice making. People who are self-determined are able to make choices according to their own thinking and are less likely to submit to outside pressure.

Group norms and school culture often create pressure for certain behaviors. Bystanders’ position-taking in bullying is very much the result of peer pressure and the desire to be accepted by peers [33]. Students are more likely to join in bullying if their social network does the same thing. Besides group norms, school culture also contributes to the social pressure on bystanders. In environments where speaking up against injustice is clearly accepted and valued, the risk of social rejection for active bystanders is reduced, whereas in environments where bullies hold the power to determine acceptance or rejection, the risks of speaking up are greater [5]. If students are well-equipped with self-determination, they are less likely to acquiesce to negative peer pressure and school culture, and are more able to take the positive side when they witness bullying.

PROJECT P.A.T.H.S.: A POSITIVE YOUTH DEVELOPMENT PROGRAM ENHANCING STUDENTS’ SELF-EFFICACY, POSITIVE IDENTITY AND SELF-DETERMINATION

Most school-bullying intervention programs, both in western countries and in Hong Kong [47,48], focus on providing social-skills training for bullies and victims, increasing students’ awareness of bullying, heightening their concern for victims, providing peer mediation programs to improve students’ intervention behavior, and creating an anti-bullying school ethos by restructuring the school environment. However, overseas evaluation studies show that these

programs do not clearly improve bullying or victimization in the schools, or that they are effective in one school but not in others [15,47,49]. In Hong Kong, few (if any) systematic studies on evaluating the bullying intervention programs have been done. The effectiveness of these programs is therefore unknown.

In view of the increasing seriousness of school bullying, Project P.A.T.H.S. – a positive youth development program in Hong Kong – includes bullying as a discussion topic in its Extension Phase [50]. To fill the literature gap [51], the P.A.T.H.S. curriculum (Appendix 1) focuses on facilitating students to become prosocial helpful bystanders. The curriculum references literature on psychoeducational programs to enhance positive identity, self-efficacy and self-determination, in combination with Salmivalli's recommendations [24] in the case of school bullying to offer (1) general awareness-raising, (2) chances for self-reflection, and (3) possibilities to rehearse new behavior.

In Secondary 1 of the new curriculum, students are introduced to basic knowledge on bullying, including what it is and what its effects are, as well as do's and don'ts when facing bullying. Through understanding the effects of bullying, students can understand how bullying harms themselves and others, in order to keep from joining in. Teaching students do's and don'ts may also help them protect themselves when being bullied. The focus shifts to bystanders in Secondary 2 and Secondary 3, with four goals: to understand that peer bystanders play an important role in bullying and can alter the outcome of bullying; to learn to be a wise and sensible bystander in school bullying; to be a responsible bystander in cyberbullying; and to learn to understand and accept the differences and constraints of others.

In addition to the new curriculum addressing bullying, the Project P.A.T.H.S. Tier 1 programs (original phase) – a universal positive youth development program for students in Secondary 1 to 3 – also help enhance participants' self-efficacy, positive identity and self-determination, aside from other essential competencies in social bonding, emotional competence, and moral judgments. For example, in the units on self-efficacy, students are encouraged to recognize their successful experiences; to experience self-efficacy through enactive attainment; to be connected to ownership in goal setting, self-regulation, and self-efficacy in goal attainment; and to manage their psychological selves in goal attainment. The units on positive identity help students to accept and appreciate themselves; to explore their ideal, actual and ought selves; and to enhance their feelings of mission. The units on self-determination focus on enhancing students' understanding of autonomy and their involvement/competence in goal setting and action planning, and on promoting students' problem-solving and decision-making skills in confronting risk-taking behaviors and undesirable peer influences.

The curricula in the original phase and in the extension phase work in a spiral manner that enhances students' self-efficacy, positive identity and self-determination and repeatedly consolidates what they have learnt year by year. The cultivation of self-efficacy and positive identity, together with the knowledge of effective intervention skills, enables students to exercise their self-determination skills in making sensible decisions and taking prosocial stands against school bullying. One caveat is that the curriculum should be applied with a gender-sensitive perspective. Some studies [52] have found that boys may have higher drop-out rates from programs that try to develop them into helpful bystanders, especially when conventional masculine role models and macho values (like those in Chinese families) prevail in society.

CONCLUSIONS

School bullying is a triadic social process, in which bystanders assume roles equal to, if not more important than, those of bullies and victims in steering the course and outcome of bullying. Fellow students, teachers and staff at school, as well as parents who interact with their children's lives at school, are all bystanders, but this paper has focused on peer bystanders. Peer bystanders' position-taking is influenced by many different physical, psychosocial and intra-psycho factors. Of these, three intra-psycho attributes – positive identity, self-efficacy and self-determination – are particularly important direct and immediate variables under the direct control of the bystander. Based on psychoeducational principles with demonstrated effectiveness in Project P.A.T.H.S., a positive youth development program assisting students in their growth to adulthood, this paper is a useful addition to the field to fill the literature gap on how peer bystanders can play a key role in ameliorating school bullying.

APPENDIX 1. BULLYING UNITS – OVERVIEW

	Unit Code/Unit Name	Construct	Unit Aim	Learning Targets
Secondary 1	AB1.1 Incidents of Bullying	Behavioral Competence, Emotional Competence, Resilience	To understand what is meant by bullying and its consequences, to avoid being a bully or a victim	1. To understand the definition of bullying 2. To investigate the behavioral and emotional reactions of the bully, the victim and bystanders in bullying incidents, and the consequences of bullying
	AB1.2 Behind the Mask of Bullying	Emotional Competence, Behavioral Competence	To understand the true needs of the bullies, and identify proper approaches to minimize bullying	1. To understand the reasons of bullying and the mentality of the bullies 2. To identify suitable approaches to fulfill the underlying needs of the bullies in order to reduce bullying
	AB1.3 A Secret Book of Bullying Prevention	Social Competence, Behavioral Competence	To learn what should be done in the face of bullying	To learn do's and don'ts in the face of bullying
Secondary 2	AB2.1 I Can Make a Difference	Moral Competence, Prosocial Norm	To understand that bystanders play an important role in bullying	1. To understand that the “bystander effect” has a significant impact on a person’s decisions and behavior 2. To understand that the consequences of a bullying incident vary with the attitudes and responses of the bystanders
	AB2.2 Make a Smart Move	Moral Competence, Behavioral Competence	To learn to be a wise and responsible bystander	1. To understand the factors affecting the attitudes and responses of bystanders to bullying incidents 2. To investigate how to stop school bullying wisely
Secondary 3	AB3.1 Online Buddies	Moral Competence	To learn to be a responsible bystander in cyber-bullying	1. To know the tremendous harm that cyber-bullying can cause 2. To investigate the proper attitude for bystanders in cyber-bullying incidents
	AB3.2 Alien?	Social Competence	To learn and practice the motto “seek common ground and respect differences; seek harmony but not uniformity”	1. To understand that everyone has his/her own limitations and is different from others. 2. To learn to understand, tolerate, and accept those who are different from us

ABSTRACT

Bullying and violence, which can bring detrimental effects, are situations which young people have to face in their process of development. Though school bullying has been a spreading and explicit problem in Hong Kong schools, most of the programs or guidelines dealing with the problem lack citywide, recognized initiatives and the effectiveness of these programs is unknown due to the lack of evaluation. The present paper discusses preventing school bullying from a developmental guidance perspective, using the positive youth development paradigm, and promoting the values of harmony and forgiveness at the whole-school level to cultivate a harmonious school culture as a way of combating school bullying.

Keywords: Bullying, forgiveness, harmonious school culture, developmental guidance, positive youth development, whole-school approach

INTRODUCTION

School bullying has become a spreading and explicit problem in Hong Kong schools and is an issue of growing concern for parents, teachers and educators [1,2]. Following the definition of Olweus [3], bullying refers to intentional, oppressive behavior against another person that causes physical and/or psychological harm. It is an abusive behavior which is typically repeated over time, that is, such behavior is not a one-time occurrence. Bullying behaviors are usually classified into one of these four categories: 1) Physical bullying refers to overt physical aggression such as hitting, pushing, kicking, spitting and punching; 2) Verbal bullying refers to overt verbal aggression such as name-calling, teasing, insulting and threatening speech; 3) Social exclusion behaviors aim to hurt the victims by damaging their peer relationships or social standing. Such behaviors include ignoring the presence of the victims, spreading hurtful rumors, excluding the victims from a friendship group, or threatening others not to play with the victims; and 4) Extortion such as asking for money or others' property [4,5]. Often, a real or perceived imbalance of power persists between the bullies and the victims [3,6]. For example, the child bullies who are older have greater physical strength and are more socially or verbally adept than the victims. Also, bullies are more psychologically manipulative, or have a higher social standing than the targeted victims [5,7].

Research studies have shown that school bullying has detrimental effects on victims and the bullies themselves as well as on bystanders, which affect their academic, social, emotional, mental, psychological functioning as well as physical health. Problems arising from bullying may persist into adulthood [6,8,9]. Factors such as students' psychosocial functioning and their accessibility to violent values are found to be related to school bullying [4,6,10,11]. Students who have unstable emotions, unsatisfactory school performance, poor relationships with their family members, teachers, and peers, are more likely to be involved in peer victimization [4]. Those who are exposed to violent values, such as growing up in an aggressive background [10,12], having frequent contact with deviant peers [13], being exposed to violence messages through the media [14,15] are more likely to engage in violence, either as bullies or as victims. Further, students lack skills and strategies to deal with incidents of bullying. Victims of bullying often develop intense anger and anxiety, and suffer low self-esteem or depression [16,17]. Some may misdirect their anger and in turn become bullies [2]. Hence, the way in which schools respond to school bullying is pertinent.

In school guidance, there have been three major approaches in dealing with student problems, including school bullying, namely remedial, preventive, and developmental guidance [18]. Remedial guidance focuses on offering interventions and therapies to students experiencing emotional, psychological or behavioral difficulties. In the case of school bullying, a remedial guidance approach focuses on the individual student level, victims as well as bullies. Such an approach is a responsive and curative approach. Preventive guidance is a proactive approach, which stresses anticipation of problems like bullying, enhancing students' awareness of bullying and victimization, and skills and strategies to handle bullying. Developmental guidance approach, on the other hand, is a positive approach to facilitate students' whole person development, including their personal, social, and moral self-formation. Developmental guidance addresses issues such as self-knowledge, self-responsibility, interpersonal relationships, bonding. These are delivered through a guidance curriculum at classroom level and school-wide programs. Through education on the need for respect for self and for others,

tolerance of individual differences, self-determination and responsible decision making, students will attain positive self and inter-personal development. Among these three approaches, developmental guidance contributes the most to the holistic development of students, is considered as one of the most effective measures in promoting students' healthy development and in preventing juvenile delinquency. Developmental guidance has been the guidance approach and focus of schools in Hong Kong and elsewhere [19].

School climate is another factor related to school bullying. Students are at a greater risk of engaging in bullying acts if in their school there are often conflicts or low morale among students and teachers. On the contrary, schools with a positive climate have less bullying-related problems, and students are more likely to engage in altruistic behavior [10,20]. These research findings point to the significance of promoting a harmonious school culture as a means of preventing school bullying. The present paper discusses preventing school bullying from a developmental guidance perspective, using the positive youth development paradigm, and promoting the values of harmony and forgiveness at the whole-school level to cultivate a harmonious school culture as a way of combating school bullying.

INTERVENTIONS TO COMBAT BULLYING

School bullying is a systemic and a complex process of social interactions that involves bullies, victims, peers, adults, parents and school as well as home environments [21]. A review of bullying intervention programs suggests that intervention may target at the individual student level, for example, teaching the victims self-assertion skills, helping the victims to deal with their negative emotions arising from being bullied, helping the bullies to develop empathy for the victims, and forming a support group involving the victims and the bystanders [22]. Such an approach is a remedial guidance approach in combating school bullying. Some interventions target at the classroom level, for example, through classroom discussion to enhance students' awareness of and developing rules to deal with bullying. Other interventions target at the whole-school level, such as devising a whole-school anti-bullying policy that is communicated to the whole school community [22]. Peer-led intervention utilizes peer support such as peer counseling to improve students' communication and empathy skills, and peer mediation to resolve conflicts. Other forms of peer-led intervention involve setting up cooperative work groups, creating a circle of friends to support students at risk of victimization [23,24]. Whole-school interventions usually target at all school members including staff, pupils and parents to enhance their knowledge and responses to bullying [3]. Since bullying springs from factors external to individual child sub-systems, bullying interventions need to involve different systems within the school community in order to have a significant consistent impact. A whole-school approach to bullying that is directed at the entire school context and involves a comprehensive, multilevel strategy that targets bullies, victims, bystanders, families, and community, becomes pertinent [21,25]. Classroom intervention and whole-school anti-bullying programs illustrate the preventive guidance approach to school bullying. These programs usually target at providing training in social skills, altering group norms and increasing self-efficacy. A review of the effectiveness of anti-bullying interventions has shown that the incidence of bullying cannot be reduced by implementing the curriculum alone [21]. Implementation of intervention across schools has a higher success rate [5], and the intervention

is most effective when the anti-bullying curriculum is integrated into the regular school curriculum [23]. School climate factors, such as interpersonal relationships and quality of communication, the important ecological factors influencing bullying, however, are not usually included in the whole-school intervention program [26]. Developmental guidance precisely addresses to building a positive school climate and a guidance oriented community where each individual's rights are respected and valued.

The spreading and explicit problem of bullying in Hong Kong schools is illustrated in a study of local secondary schools, which found that over half of the respondents were involved in bullying [1]. In another study, it was found that nearly 90 per cent of the respondents witnessed verbal bullying in the past half year, and nearly 70 per cent of the respondents experienced physical bullying in the same period [4]. In another study on cyber-bullying, 22 per cent of the respondents bullied others, 30 per cent of the respondents were being bullied, and nearly 60 per cent witnessed cyber-bullying in the past one year [27]. However, it was not until recently that some programs or guidelines dealing with the problem of school bullying were developed by the governmental authorities and the local practitioners [28-32]. Nevertheless, most of the programs lack citywide, recognized initiatives [1], and the effectiveness of these programs is unknown due to a lack of evaluation. Anti-bullying intervention has focused on the individual student level, adopting a suppressive strategy. Such an approach is bully-focused and blame-driven. Measures such as withdrawal of privileges, meeting parents, school suspension and expulsion have been adopted by schools to deter students from bullying. However, this strategy is considered punitive and may worsen the bully-victim relationship or even intensify the problem [1,23]. Such an approach is also very remedial and reactive in focus, falling short of teaching bullies and victims' skills for dealing with conflicts. Another approach is a comprehensive anti-bullying strategy which aims to tackle risk factors contributing to bullying, and to involve all people in the whole school [1]. Four useful tactics underlying this strategy are: (1) Encouraging victims to tell the truth and develop a strong character; (2) Educating bullies who lack social skills; (3) Shaming bullies who intend to do harm, or who have done harm, in a re-integrative manner; and (4) promoting a peaceful environment by using restorative practices [1, p.546]. Such an approach focuses on prevention of the problem and functions more like preventive guidance in schools. There has been insufficient integration of anti-bullying initiatives into schools' policy from a developmental guidance perspective as a means of strengthening students' personal and social development. There has also been a lack of intervention at the classroom level, such as incorporating an anti-bullying curriculum into the school's regular guidance curriculum, and a similar lack of intervention at the whole-school level through promoting a harmonious school culture. A guidance curriculum which focuses on developing students' strengths and the values of harmony and forgiveness will help address the problem of bullying from a developmental guidance perspective.

TACKLING BULLYING FROM A POSITIVE YOUTH DEVELOPMENT PERSPECTIVE

Positive youth development (PYD) focuses on developing adolescents' strengths and competencies, personal character, social connections, and the ability to care and contribute to

society through a planned curriculum and program [33]. Developing adolescents' assets and strengths is important [34]. It is asserted that the achievement of the above developmental tasks will increase adolescent psychosocial well-being and societal well-being. The goals of PYD are very similar to those of developmental guidance, for both are positive approaches to facilitate the whole-person development of young people via a systematic and planned school guidance curriculum [18]. Both PYD and developmental guidance stress the importance of focusing on strength and on developing competence. Such a positive approach, which is not 'problem driven', is particularly relevant in combating problems like bullying in schools.

Catalano, Berglund, Ryan, Lonczak, and Hawkins [35] identified fifteen psychological constructs or competencies as the key elements of the successful positive youth development programs. Constructs which promote inter-personal relationships, such as bonding, recognizing positive behavior, fostering pro-social involvement and pro-social norms, and those which promote emotional, moral, social and behavioral competence contribute to building strengths in adolescents which will serve to counteract bullying and other forms of school violence.

To promote the holistic development of adolescents in Hong Kong schools, the "P.A.T.H.S. to Adulthood, a Jockey Club Youth Enhancement Scheme" has adopted the positive youth development paradigm and devised a curriculum incorporating the fifteen psychological constructs. The Tier 1 program of Project P.A.T.H.S., a universal positive youth development program, functions like a developmental guidance curriculum for all students. Issues that adolescents may face, such as sexuality, concepts of money and success, bullying, internet addiction, substance and drug abuse, are incorporated as examples and illustrations in the program, with an attempt to promote students' psychosocial competencies [36]. The evaluation findings consistently show that Project P.A.T.H.S. is effective in promoting positive youth development [37-42]. Specifically, positive effects in reducing adolescent delinquent behavior among the junior secondary years have been found [48].

The newly devised P.A.T.H.S. units, which address to bullying share functions similar to a classroom-based intervention. As shown in Table 1, these units aim to enhance students' understanding and awareness of the nature of bullying and cyber-bullying, the needs of the bullies and the victims, the role of the bystanders in bullying, the moral responsibility in stopping bullying, the respect of others and cyber ethics. As a PYD program, these units foster specifically the psychological constructs of bonding, resilience, social competence, emotional competence, behavioral competence, moral competence, and pro-social norms. Since these units are taught as a classroom curriculum for all students in their respective class levels, the students will acquire competence, positive skills and strategies in facing bullying and school violence. Hence, these PYD units also tackle bullying from a developmental guidance perspective through a systematic curriculum targeting at all students.

There are several merits in adopting the positive approach in tackling bullying. First, it addresses bullying from a positive youth development paradigm, stressing the importance of competency building. Issues relating to bullying are used as a context through which students learn appropriate social skills, emotional management skills, and the ability to understand others' emotions, to appreciate and forgive others. In addition, units target at helping students to explore proper attitudes and skills when facing unjust and violent situations, to learn to see things from other people's perspectives, and consider appropriate ways of responding. Through enhancing students' moral, social and behavioral competence, the incidences of bullying can be prevented. Second, this is a deliberate attempt to incorporate anti-bullying elements in a form of classroom curriculum to be delivered in the schools' regular curriculum. Enhancing

students’ knowledge about bullying and positive ways of handling it through classroom discussion and activities is more effective as an intervention strategy [23]. Students can be equipped with knowledge and skills to foster a positive and culturally appropriate learning environment. Cooperative group work and activities which enhance students’ intrapersonal and interpersonal skills can reduce the extent of victimization of vulnerable students and promote a peaceful, loving, and respectful classroom environment [4]. Third, building students’ assets and strengths in inter-personal relationships, bonding and competence will help build a caring school ethos, leading to a more harmonious school culture.

Table 1. An overview on the foci of the P.A.T.H.S. units on bullying

Level	Goals	Constructs
Secondary 1	1. To understand what is meant by bullying and its consequences, to avoid being a bully or a victim 2. To understand the true needs of the bullies, and identify proper approaches to minimise bullying 3. To learn what should be done in the face of bullying	Emotional Competence, Behavioral Competence, Social Competence, Resilience
Secondary 2	1. To understand that bystanders play an important role in bullying 2. To learn to be a wise and responsible bystander	Moral Competence, Behavioral Competence, Prosocial Norms
Secondary 3	1. To learn to be a responsible bystander in cyber-bullying 2. To learn and practice the motto “seek common ground and respect differences; seek harmony but not uniformity”	Moral Competence Social Competence

TACKLING BULLYING THROUGH CULTIVATING A HARMONIOUS SCHOOL CULTURE

Bullying behavior is influenced by the social context [44]. A positive school climate can reduce aggression and bullying as well as promote positive youth development [22,25,45]. In addition to the integration of an anti-bullying curriculum with a positive youth development program like Project P.A.T.H.S., as mentioned above, other strategies can be adopted to complement this approach in order to cultivate a caring school climate which values harmony, with zero tolerance towards violence.

Fostering Forgiveness as a Value and Coping Strategy

Forgiveness is a moral concept and a moral response to interpersonal conflicts and injustice. Forgiveness is defined as a replacement of negative sentiments with positive affect,

thinking and behavior towards the offender [46]. In forgiving, the offended becomes less motivated to do harm and more motivated to do positive things to benefit the offender [47]. Forgiveness is not excusing, condoning or justifying the unjust offences. Rather, forgiveness is a strategy to reduce stress arising from the transgression and the unforgiving emotions. The victim may employ decisional forgiveness, that is, having the intention to give up revenge or avoidance towards the offender, and emotional forgiveness, which is replacing negative with positive emotions [48]. Forgiveness interventions have been used with adults and college students to deal with hurts and offences [see 49,50]. Recently, forgiveness interventions following Enright's process model have been used with children and adolescents [51-54]. In Hong Kong, forgiveness has been introduced as a developmental guidance curriculum for adolescents [55] and as a small group preventive guidance intervention with children who judged themselves to have been hurt and chose not to forgive the offenders [56]. Both studies adopted Enright's process model and implemented forgiveness education as school guidance programs. The results indicated that those who received the forgiveness programs outperformed their counterparts in forgiveness attitude, conceptual understanding of forgiveness and psychological well-being. Specifically, these students learnt empathy as a key strategy to forgive and indicated more readiness and confidence to apply forgiveness as a strategy in dealing with offences in future.

Ahmed and Brathwaite [57] suggest the link between forgiveness, reconciliation and reducing bullying. The absence of forgiveness and reconciliation makes no contribution to building emotional scaffolding. Egan and Todorov [5] further suggest that forgiveness can be introduced as a strategy to help students respond to being bullied. Anti-bullying intervention with individual students may incorporate forgiveness as an element to help victims to deal with stress and negative emotions. This will have the benefit of deterring victims from turning into bullies. Klatt and Enright [58] suggest that forgiveness can be conceptualized from a positive youth development perspective for education. Forgiveness is not yet included as a psychological construct within the positive youth developmental paradigm, though Project P.A.T.H.S. does include a unit on forgiveness.

Introducing forgiveness as a developmental guidance curriculum has several benefits. First, conceptualizing forgiveness from a PYD perspective will contribute to fostering forgiveness as a strength and asset, not only for victims and those at risk of school violence, but for all students. Strategies such as empathy and reframing will benefit not only victims, but also potential bullies and bystanders in their responses to offences and unjust situations. Forgiveness is a choice and a decision. Teaching young people forgiveness as a strategy in dealing with interpersonal conflict will increase their behavioral and emotional competence. Second, teaching forgiveness as a value and a coping strategy can help students to be less inclined to seek revenge and retaliation in inter-personal conflicts and to be more positive and proactive in seeking harmony. Hence, incorporating forgiveness as a guidance curriculum that targets the whole-school community will help promote a more caring, tolerant and responsive school climate.

Social Support of Teachers

Social support has been found to be an important contextual factor in countering bullying, yet there is a lack of explicit application of social support in anti-bullying programs and interventions [59]. Research studies have demonstrated that students' perceived school

satisfaction is related to supportive teacher-student relationships [60], teacher support [61], and a caring and supportive school climate [62]. Teacher support has been found to be a protective factor against students' suicidal ideation [63], has acted as a significant predictor to students' perceived school satisfaction [64], and played a mediating role in the relationship between victimization and school maladjustment [59]. However, not all teachers perceive bullying as serious, know how to intervene and prevent bullying, or have the confidence to manage disruptive behavior [65]. This points to the importance of educating teachers about bullying and strengthening teachers as support in the school setting. A whole-school intervention program by Olweus [3] incorporated teachers to provide support on the whole-school level by, for example, identifying bullying incidents, providing increased supervision in secluded areas and coordinating with parents, school staff and students. On the classroom level, teacher support includes establishing class rules against bullying, setting consequences for violating the rules. However, just setting rules or a one-off discussion in the classroom or on the whole school level is not sufficient. Involving teachers in delivering guidance programs addressing bullying has further benefits. Teachers may integrate anti-bullying themes within the school developmental guidance programs and values education programs, so that non-violence and tolerance can be presented as a consistent message to all students and highlighted as the ethos of the school. Also, teachers act as a role model for students. Supportive teacher-student relationships will encourage students, whether victims or bystanders to seek help. Teachers may foster attitudes such as acceptance, respect, tolerance and forgiveness and relate their importance to inter-personal relationships and social harmony. On the individual student level, teachers may offer support to bullies, victims, the peers of bullies and victims, in dealing with bullying and conflicts. Involving teachers systematically on all three levels is a more comprehensive strategy to prevent bullying. As peer victimization is an important determinant leading to school dissatisfaction [66] and peer conflicts lower students' liking of their schools [67], on-going efforts and social support from teachers are pertinent to building a positive and caring classroom and school climate.

Involving Peers as a Support

Students value having a peer listen to their experience of being bullied [24]. Peer-led anti-bullying interventions, such as peer counseling and peer mediation have been found to have positive outcomes, which also lead to an improvement of the school climate [23]. Students who used peer counseling for bullying service identified as pertinent such characteristics as peer counselors having good listening skills, being trustworthy, maintaining confidentiality, and providing advice on solving bullying-related problems [68]. Peer counseling has been used increasingly in schools in Hong Kong and elsewhere as a form of peer support to facilitate junior students' adjustment and learning. Such support can be extended to include antibullying. In addition to training peer counselors' skills, such as active listening, empathy, problem solving, the units which address school bullying in the Project P.A.T.H.S. can be incorporated in the training program to enhance peer counselors' knowledge and understanding of the nature of bullying, the feelings and emotions of the victims, the needs and mentalities of the bullies, and proper approaches to minimize bullying. However, the support of adults such as teachers and social workers is essential. Further, support needs to go beyond peer counselors for bullying service to other peers in the school community, for not all students use peer counseling due to

the fear of being stigmatized [68]. The Project P.A.T.H.S. includes units addressed specifically to the role of bystanders in bullying, factors affecting the attitudes and responses of bystanders to bullying incidents. All students, whether victims, bullies or bystanders will be taught explicitly in classroom guidance programs about bullying as a form of violence and its effects on the school community. Such an approach targeting all students will further enhance peers as a support system in the school community. Further, school-wide developmental guidance programs educating students about respect for individual differences and the value of harmony, justice and responsibility will help to build a more tolerant and caring school climate.

Promoting Non-violence and Harmony as a Whole-school Approach to Counter Bullying

Research and practices in school guidance and pastoral care have affirmed the importance of having a whole-school approach in facilitating students' whole-person development [18,19,69]. Under the framework of a whole-school approach, guidance and supports are provided to all students, not merely students who are at risk, and is a responsibility of all teachers, not only the guidance personnel and professionals. Guidance can be delivered at individual student level, classroom and whole-school levels. Developing a systematic and planned guidance curriculum, and integrating guidance themes into the school's formal and informal curriculum are essential elements under this framework. Such an approach also requires school to have a whole-school policy which details the goals, system of management, co-ordination and communication among teachers, parents, and professionals. Promoting a whole-school approach to guidance is a way to cultivate a positive school ethos [18]. Hence, this approach is very much in line with promoting non-violence and harmony as a positive way to combat school bullying.

Cultivating a harmonious school culture needs to be done as a whole-school approach, ranging from the individual student level, class level to the school-wide program level as discussed above. Such an endeavor needs to be further supported at the whole-school system level. First, a whole-school policy which stresses non-violence and tolerance needs to be integrated with the school's guidance policy, so that there will be consensus and consistency among all staff in their responses to the problems of bullying and peer victimization and the promotion of non-violence. Such a policy needs to be communicated to the students and parents. Second, in addition to cultivating the values of harmony and non-violence through school's values and moral education curriculum, the implementation of the PYD anti-bullying program at classroom level which fosters students' bonding, competencies and self-determination, will contribute to a more positive and caring class ethos. Further, the integration of themes such as respect, tolerance, forgiveness, justice with academic subject teaching will help enhance effectiveness, for the teaching of values must be ongoing and integrated into the school curriculum so that the values can be kept front and center [23]. Third, on the management level, another essential element that needs to be dealt with from a whole-school system perspective is collaboration with professionals such as school psychologists, school counselors and social workers in issues such as identifying students at risk of bullying and victimization and offering timely intervention. The implementation of Tier II program of Project P.A.T.H.S., for example, will require teachers and professionals to work in collaboration. Fourth, as mentioned above, teachers play a very important role in fostering

values through classroom teaching, delivering classroom guidance programs such as the PYD anti-bullying programs and forgiveness education. This will require school to plan and organize professional development programs to enhance teachers' knowledge and skills and to offer individual support. Involving peers as support and working with parents are other essential elements under the framework of a whole-school approach, which have been adopted in whole-school anti-bullying intervention. Lastly, the involvement of the entire school community, students, parents, teachers, administrators, professionals and adjunct school staff in the practice and support of such a school policy is pertinent to building a safer, more caring, responsive and harmonious school culture. [23]. Combating bullying as a whole-school approach to guidance is a matter of cultivating a guidance-oriented ethos, in which concern, love and compassion are advocated as values for students' whole-person development.

CONCLUSIONS

Bullying and violence are situations which many young people have to face in their process of development, whether as bullies or victims or bystanders. A more proactive way to prevent bullying is to adopt a developmental guidance approach to strengthen young people's skills and competencies in inter-personal relationships and bonding. Programs, which, like Project P.A.T.H.S., adopt a positive youth development paradigm and implement it as a classroom developmental guidance curriculum are a proactive approach to counter bullying. Cultivating a school environment which cherishes forgiveness and harmony, endorses respect, non-violence, tolerance and compassion is another important strategy. This will require a systematic approach to strengthen teachers and peers as social support, and will involve the entire school community on the policy, management and implementation levels to promote a caring school culture as a proactive way to tackle bullying.

Chapter 61

DETERMINING ADOLESCENTS' RISK FOR INVOLVEMENT IN BULLYING OR CYBERBULLYING: A REVIEW OF TWO STUDIES

***Elizabeth L. W. McKenney*, Amanda M. Cole,

and Jeremy D. Jewell***

Southern Illinois University Edwardsville, US

ABSTRACT

As increasing attention is paid to the issue of bullying and cyberbullying in school-age populations, additional knowledge is needed regarding groups of students who are most likely to be involved in bullying. Involvement in bullying can include traditional forms of physical and verbal aggression, or can include cyberbullying. This chapter summarizes a series of studies investigating the role of gender, time spent online, time spent sending and receiving text messages ("texting"), parenting styles, and relationship dynamics within families in predicting involvement in bullying either as a bully or as a victim. Traditional bullying and cyberbullying were examined, and some important differences between bullying formats were observed regarding risk factors. Engaging in cyberbullying as a bully was more common among male, high school or college students; overall bullying (either traditional or digital) was associated with an authoritarian parenting style. Implications of these findings for practitioners include the need to attend to demographic characteristics in identifying targeted groups for prevention programs, and the potential importance of parent training as part of intervention with students who are already engaged in bullying. With regard to victimization, frequency of digital communication via instant messaging and text messaging predicted cybervictim status, with frequency of text messaging being the most significant predictor of cybervictimization. Family interaction patterns characterized by conflict within the family environment were predictive of victimization both traditionally and digitally. Finally, cohesion among family members was negatively correlated with both bullying and victimization in both formats. This finding indicates that there may be

* Corresponding Author's Email: elmcken @siue. edu.

important skills taught in either emotional regulation or social interaction within cohesive families that serve to reduce adolescents' involvement in bullying. Implications for future research into school- and community-based interventions targeting family interaction patterns and important skills in preventing or reducing bullying are discussed.

INTRODUCTION

The issue of bullying is one of the fastest growing areas of educational policy-making and research. Due to several high profile incidences of student suicide related to bullying or cyberbullying in recent years, increasing attention has been paid to this issue at all levels including state legislation, educational and psychological research, and school-based intervention programs. Bullying is perhaps best defined as, "... aggressive behavior or "harm doing" by one person or a group, generally carried out repeatedly and over time, and which involves a power differential," (Hinduja & Patchin, 2010, p. 207). Cyberbullying expands on this definition by specifying the use of computers, cell phones, and other electronic forms of communication in a similar pattern of "willful and repeated harm," (Hinduja & Patchin, 2010, p. 208). Nationally representative studies of prevalence indicate that bullying peaks in early to mid-adolescence, during the middle and high school years (McKenna, Hawk, Mullen, & Hertz, 2011; Ybarra & Mitchell, 2004). Thus, both bullying and cyberbullying pervade throughout adolescence and can inflict serious emotional harm upon students throughout middle and high school.

In contrast with traditional popular beliefs that bullying is a predominantly male behavior involving physical harm and aggression toward others, it is now widely accepted that bullying occurs among both male and female peer groups. Although generally females are more likely to engage in relational aggression (gossiping, spreading rumors, excluding victims from socially desirable activities or groups; Li, 2005), males may also engage in relational forms of aggression, and female adolescents can and are at times physically aggressive toward their victims. Given the indirect nature of cyberbullying, relational aggression in particular is of rising concern among both male and female adolescent groups (Li, 2005).

PREVALENCE

An expansion of research into bullying has yielded new knowledge about the frequency of both bullying and cyberbullying among adolescents in many countries throughout the world. Upon looking across the prevalence rates reported by numerous researchers investigating the prevalence of cyberbullying among U. S., Canadian, and Chinese populations, Hinduja and Patchin (2010) determined that approximately 15 - 35% of students studied report cybervictimization, while 10 - 20% report cyberbullying others. A recent investigation with Taiwanese junior high school students (7th through 9th grades) yielded similar findings: 34.9% of those studied reported ever having experienced cybervictimization (Li, 2010).

Recent investigations into the prevalence of bullying on school campuses, which is considered to primarily reflect traditional forms of bullying, reveal similar results. In 2005, Due et al. studied the prevalence of bullying among adolescents in Israel, Russia, the United States, Canada, and 24 European countries. In their study, the prevalence of bullying ranged from a

low of 6.3% of 11, 13, and 15 year old girls in Sweden to a high of 41.4% of 11, 13, and 15 year old boys in Lithuania. Dinkes, Cataldi, and Lin-Kelly (2007), reporting on multiple surveys and databases collected by public health and justice agencies in the United States, found that an average of 28% of youth ages 12 - 18 reported being bullied in 2005, approximately 8% of whom reported being bullied almost daily. All studies described above included a roughly equal number of male and female participants, and the literature remains inconclusive as to whether male or female students engage in higher rates of bullying and cyberbullying (Li, 2010).

SEQUELAE

The consequences of bullying range from more mild forms of emotional distress to severe mental health problems, including depression, suicidal ideation, and attempted and completed suicide. A considerable body of research has demonstrated that involvement in bullying is related to several psychological indicators of distress. As summarized by Hinduja and Patchin (2010, p. 207), "... experience with peer harassment (most often as a victim but also as a perpetrator) contributes to depression, decreased self-worth, hopelessness, and loneliness - all of which are precursors to suicidal thoughts and behavior." While suicide related to bullying and cyberbullying is certainly of greatest concern, its incidence among students who are involved in some form of bullying remains relatively rare. Nevertheless, international research summarized by Hinduja and Patchin (2010) indicates that students who are bullied experience rates of suicidal ideation somewhere in the ranges of 4 - 18%, and are three to four times more likely to have suicidal ideation than their non-bullied or bullying peers.

In a study conducted in the Netherlands, a slightly larger percentage of boys who were bullied indirectly reported suicidal ideation than those who were bullied directly (18% versus 13%, respectively; van der Wal, de Wit, and Hirasing, 2003). Although an early study with respect to the rise of cyberbullying, these effects may indicate that the emotional sequelae of cyberbullying can be more pervasive and devastating than those typically produced by bullying. A recent analysis of survey data collected in 2005 revealed that middle school students involved in cyberbullying, either as victims or as bully victims, reported higher levels of depression than students who only reported involvement in traditional bullying (Wang, Nansel, & Iannotti, 2010). Researchers have posited that the greater reports of emotional distress as a result of being victimized by cyberbullying may be due to the seemingly inescapable nature of the bullying (i.e., it can be experienced at home, school, or any other location) and the permanence of the bullying acts themselves, as they can be repeatedly accessed via electronic communication devices and websites. Given several high-profile incidences of suicide related to cyberbullying in recent years, or cyberbullicide, the apparently stronger link between cyberbullying victimization and more severe forms of depression merits particular attention (Hinduja and Patchin, 2010).

The act of bullying itself may also be linked to more severe forms of aggression in later adolescence or adulthood. Espelage, Basille, and Hamburger (2012) recently reported on early results in a longitudinal study examining the degree to which perpetuating bullying is linked to homophobic bullying and sexually harassing statements to peers. They posit that a link between bullying, homophobic bullying, and sexual harassment may result in a higher perpetuation of

sexual violence among students who engage in bullying when in middle school. Their results indicate strong correlations between bullying and homophobic teasing and between bullying and sexually harassing statements, providing initial support for their proposed model of developing sexual violence. As more data is gathered and reported, additional attention should be paid to the extent to which bullying may predict sexual violence later in adolescence and adulthood. The possibility of a link between the two behaviors underscores the need to more thoroughly understand bullying and cyberbullying, and to develop effective intervention protocols that strengthen alternate forms of adolescent peer interactions.

INTERVENTIONS ADDRESSING BULLYING AND CYBERBULLYING

In response to the continuing need to respond to and attempt to prevent bullying within the school context, several programs have been developed at all levels of the K-12 curriculum that can be effective at preventing bullying and cyberbullying, and decreasing participation in both forms of aggression when they are already present. Programs targeting youth violence, including bullying and cyberbullying, are evaluated via a cooperative effort under the direction of the United States Department of Justice to identify those programs that demonstrate the strongest and most consistent evidence of efficacy in preventing and decreasing bullying in schools (Evidence-Based Program Directory). Prevention programs are evaluated on a scale of one to three, on which Level 1 is characterized by consistently high fidelity in implementation, robust empirical findings, and sophisticated experimental evaluation procedures. Programs classified at Level 2 feature adequate fidelity, empirical findings, and sufficiently strong experimental procedures (e.g., quasi-experimental designs). Programs placed at Level 3 have demonstrated generally positive results, but often with minimal fidelity, mixed empirical findings, and limited experimental procedures (Evidence-Based Program Directory). Of those programs evaluated for their potential to decrease school violence, three are specific to bullying and have demonstrated evidence of efficacy at a classification of Level 2. No programs specific to bullying have been classified at Level 1.

The three programs at Level 2 are Steps to Respect®: A Bullying Prevention Program, Olweus Bullying Prevention Program, and Success in Stages®. While the Olweus program was initially developed in Norway and extensively researched in Europe before being applied to the United States, both the Steps to Respect® and Success in Stages® programs were developed and researched in the United States. Details regarding each program, including the intended age range, general procedures for implementation, and evidence of efficacy, are provided below. Generally, each program emphasizes increasing adult awareness of bullying, and increasing both student and adult awareness of how bullying negatively impacts others and the school environment. The Olweus and Steps to Respect® programs emphasize increasing student skill in recognizing and responding to bullying, while the Success in Stages® programs focus greater attention on individual recognition of the need to change one's behavior (i.e., bullying) and the steps necessary to effectively navigate that change.

The Olweus program has undergone the most attempts at replication and has consistently demonstrated encouraging results. The program emphasizes intervention at the school, classroom and individual levels via increased adult awareness of bullying and engagement in changing bullying within the school environment. Intervention and prevention components are

specifically designed for students between the ages of six and 14; indicating that the program is primarily designed for elementary and middle school populations. The program begins with an assessment of the extent of bullying within a school via a questionnaire distributed to students. Program components include developing specific rules regarding bullying, classroom meetings to address bullying and other climate issues, increased monitoring of areas of the building where bullying is most likely to occur, and meetings with parents to share information across contexts. A coordinating committee is responsible for overseeing and evaluating the success of prevention efforts. Efficacy of the Olweus Bullying Prevention Program has been shown to be the greatest in Norway, where the program was developed, with somewhat less success in other European countries, and the most limited impact in the United States (Suicide Prevention Resource Center, 2011). Specifically, the Olweus program appears to be most effective at increasing awareness of bullying and its consequences, and at changing attitudes regarding the acceptability of bullying. However, especially in the United States, the Olweus program has been less successful in decreasing reports of victimization and other indications of delinquent behavior, and may not produce effects that are sustained over time without ongoing consultation and support (Melton et al., 1998).

Steps to Respect® also aims to increase adult awareness of and responsiveness to bullying, and to foster beliefs among students that encourage responsibility for intervening with bullying when it occurs. The program stresses the development of social-emotional skills that assist students in handling bullying directly, including via intervening as bystanders and reporting to adults. At the outset of the program, all staff members in the school building are trained in its implementation, which is followed up on by two in-depth trainings for administrators, mental health professionals, and teachers. Teachers go on to implement 11 skill-based lessons that take 20 – 30 minutes, and two literature based units, for which the lessons last 30 – 40 minutes. Steps to Respect® is intended for use with students ages eight to 12 years old, targeting upper elementary and early middle school students. Evaluations of the outcomes of Steps to Respect® were promising when efficacy of the program was compared via randomized trial between six schools receiving the program and six wait-listed control schools. Students reported greater responsibility as bystanders, improved perceptions of adult responsiveness, and less overall acceptability of bullying. Playground observations of bullying and bystander behavior also indicated improvements. However, self-reported bullying and teacher descriptions of social interactions did not reveal any differences over the course of intervention (Evidence-Based Program Directory). Additionally, in a one-year trial, Steps to Respect® was shown to be effective at decreasing rates of malicious playground gossip (a form of relational aggression) among elementary students who participated, an effect that was not observed in randomly assigned control groups (Low, Frey, & Brockman, 2010).

Success in Stages® is a computer-based intervention program that tailors its activities to both students' grade level and their responses to survey items about their understanding of and involvement in bullying. The program has different procedures and activities that can be used with students from nine to 18 years old. Build Respect, Stop Bullying® includes two programs targeting either elementary or middle school students, while Building Respect® is specifically aimed at high school students. All the interventions involve at least three half hour computer sessions that are distributed throughout the school year. The program itself, while it asks about bullying and victimization, is based upon theories of how people proceed through change, and different stages of participation in change. Students receive feedback and additional instruction regarding their bullying behaviors based upon where their survey answers indicate that they

fall on the continuum of change. Supportive materials are also included for school personnel and others who may have direct contact with students engaged in or affected by bullying (Evers, Prochaska, Van Marter, Johnson, & Prochaska, 2007). Evaluation of the outcomes of Success in Stages[®] was done primarily on the computer-generated self-reports of middle and high school student participants, and the percentages of students who reported no longer being a bully, victim, or passive bystander were compared across intervention and control groups. The intervention group members reported significantly less bullying, victimization, and being a passive bystander from the control group once the intervention was implemented. Often, participants in the intervention groups began to report lower participation in bullying following the second lesson in the intervention series (Evers et al., 2007).

IDENTIFYING RISK FACTORS FOR INVOLVEMENT IN BULLYING

If intervention programs are to be effective at decreasing the extent to which children and adolescents are involved in bullying and cyberbullying, intervention providers must be knowledgeable of and able to recognize factors that make a student or group of students more likely to be at risk of involvement in bullying or cyberbullying. Recent research into some of the situational and historical factors that may affect adolescents' involvement in bullying and cyberbullying provides new insight into the mechanisms through which bullying occurs and might be intervened upon. Two recent studies in which such issues were examined shed light on when and how specific students may benefit from targeted interventions designed to reduce involvement in acts of bullying and vulnerability to victimization, in both traditional and electronic forms. Study 1 focuses on age and gender differences related to cyberbullying, and examines the use of pictures and videos in cyberbullying. Study 2 examined how context variables, such as family environment and parenting style, affect adolescents' participation in bullying and cyberbullying.

Study 1

Study one examined age and gender differences related to cyberbullying, as well as how access to technology, specifically frequency of technology use, impacts the likelihood of engaging in cyberbullying or cybervictimization. Additional analyses were conducted to determine how those variables may be related to image cyberbullying and cybervictimization, which is specific to posting or sending embarrassing pictures of someone, and/or video of someone being assaulted in some way (e.g., hit or beat up) in order to hurt or embarrass them. Before the onset of the study, approval was obtained through the appropriate Institutional Review Board. Participants for this study included 286 junior high and 87 high school students from three areas: schools in the northwestern suburbs of Chicago, schools in a small town in rural central Illinois, and schools in suburban southern Illinois. Also, 110 college-aged students were recruited from undergraduate psychology courses at a mid-western university. College-aged participants received class credit for participation. Overall, there were slightly more female participants than male participants. Over half (58.8%) of the participants were in junior high school. Before collecting data, informed consent forms were sent home to obtain parental

permission to participate in the study for participants under the age of 18. Those students under the age of 18 who returned the completed informed consent were allowed to participate in the study. Students 18-years-old and older were allowed to sign their own informed consent; assent was provided by participants who were under 18-years-old. The homeroom or study hall teacher passed out both the assent forms and the surveys. After obtaining informed consent and/or assent, all participants were asked to complete the *Demographic Information and Access to Technology Survey* and the *Cyberbullying Survey*. The participants took approximately 5 minutes to complete the study. For college-aged students, data were collected in the same manner except that they all were able to sign their own informed consent.

Students at the middle school, high school, and college levels were surveyed, and asked to reflect upon a variety of behaviors, including frequency of electronic communication, frequency of cyberbullying, cybervictimization, image cyberbullying, and image cybervictimization over the course of the past year, as well as demographic information including age, ethnicity, sex, and grade. Frequency of electronic communication was assessed with questions about how often students used an instant messaging program per day, the number of text messages sent per day, and the number of hours per day spent online. Cybervictimization and cyberbullying were assessed using the *Cyberbullying Survey*, which was adapted and simplified from Bilyeu's *Traditional Bully and Cyber-bully Questionnaire* (2007). The *Cyberbullying Survey* is made up of Cyberbully, Image Cyberbully, Cybervictim, and Image Cybervictim subscales. The Cyberbully and Cybervictim subscales each contain ten questions that related to cyberbullying behaviors. Questions asked about spreading gossip or rumors, threatening or insulting someone, giving out private information, using deception, and socially excluding others via electronic methods of communication. Questions regarding cyberbullying began with the phrase, "In the past year, *I have* used the internet or a cell phone to..." while questions about victimization began, "In the past year, *someone else* used the internet or a cell phone to..." Each question was answered using a 5-point Likert scale on which 0 = Never, 1 = Rarely, 2 = Once a month, 3 = Once a week, 4 = Once a day, and 5 = Several times a day. Cronbach's alphas were $\alpha = .85$ for each subscale. The Image Cyberbully and Image Cybervictim subscales each contained three questions; Cronbach's alphas for those subscales were $\alpha = .83$ and $\alpha = .72$, respectively. Responses ranged from 0 - 50 for the Cyberbully and Cybervictim Subscales; and from 0 - 15 on the Image Cyberbully and Image Cybervictim subscales.

Relatively few participants reported experience with cybervictimization and cyberbullying, and even fewer reported cybervictimization or bullying through use of an image. Means and standard deviations for each subscale are reported in Table 1.

Age, gender, frequency of using an instant messaging program, frequency of texting, and time spent online were all significantly correlated with being a cyberbully. In the case of cybervictimization, only frequency of using an instant messaging program and frequency of texting revealed significant correlations. Age, gender, and frequency of text messaging were associated with using an image to cyberbully someone; frequency of texting and time spent online were significantly correlated to being a victim of cyberbullying via an image. Frequency of text messaging was a significant correlate of overall involvement in both forms of cyberbullying and cybervictimization. Correlation coefficients are presented in Table 2.

Table 1. Means and standard deviations observed across subscales of the Cyberbullying Survey

Subscale	Mean	Standard Deviation	Potential Range
Cyberbully	2.81	4.40	0 - 50
Cybervictim	3.85	4.93	0 - 50
Image Cyberbully	.33	1.23	0 - 15
Image Cybervictim	.25	.95	0 - 15

Table 2. Correlations between demographic information, access to technology, and Cyberbully Survey subscale scores

Variable	Cyberbully	Cybervictim	Image Cyberbully	Image Cybervictim
Age	.17**	.06	.08**	.02
Gender	-.13**	-.03	-.12**	-.05
Instant Messaging	.11*	.18**	-.02	.05
Text Messaging	.26**	.30**	.14**	.08**
Time spent online	.09*	.07	.02	.11**

Note: * = $p < .05$; ** = $p < .01$. Male = 1. Female = 2.

Four simultaneous multiple regression equations were calculated to determine the influence of gender, frequency of instant messaging, frequency of texting, and amount of time spent online on cyberbullying and cybervictimization. A simultaneous regression was chosen because no theory of which predictors have the greatest or least influence on either of the criterion variables (cyberbullying or cybervictimization) has emerged. Gender, frequency of instant messaging, frequency of texting, and time spent online were predictors. Results of regression analyses are presented in Table 3.

Gender, frequency of instant messaging, frequency of text messaging, and time spent online were entered as predictors into a simultaneous regression equation to determine their influence upon cyberbullying, cybervictimization, image cyberbullying, and image cybervictimization. Results indicated that being male, texting more frequently, and spending more time online were related to increased cyberbullying behaviors, while frequency of using an instant message program was not a significant predictor of cyberbullying. With regard to image cyberbullying, being male and texting more frequently were related to increased image cyberbullying behaviors, while frequency of using an instant message program and time spent online were not significant predictors. In the area of victimization, more frequent instant messaging and texting predicted cybervictimization; time spent online and being male were not predictors. Finally, with regard to image cybervictimization, time spent online and frequency of texting were predictors, while gender and instant messaging frequency were not.

Table 3. Simultaneous multiple regression analyses examining impact of gender and access to technology variables on cyberbullying, image cyberbullying, cybervictimization, and image cybervictimization

	<i>Cyberbully Subscale Score</i>				<i>Image Cyberbully Subscale Score</i>				<i>Cybervictim Subscale Score</i>				<i>Image Cybervictim Subscale Score</i>

<i>F</i>	15.07***				6.16***				14.13**				2.87*			

Note: * = $p < .05$; ** = $p < .01$; *** = $p < .001$. Male = 1. Female = 2.

Table 4. Results of ANOVA analyses examining the effects of age on cyberbullying, image cyberbullying, cybervictimization, and image cybervictimization

	Cyberbully	Cybervictim	Image Cyberbully	Image Cybervictim
<i>F</i>	37.28	4.65	14.47	.23
<i>P</i>	<.001	<.01	<.001	=.77
η^2	.14	.02	.06	.001

Table 5. Means and standard deviations observed across subscales of the *Cyberbullying Survey* and the *Traditional Bullying and Victimization Survey*

Subscale	Mean	Standard Deviation	Potential Range	Observed Range
Cyberbully	1.22	2.47	0 - 50	0 – 14
Cybervictim	3.27	5.04	0 - 50	0 – 27
Traditional Bully	2.44	3.50	0 - 45	0 – 17
Traditional Victim	5.57	6.16	0 - 45	0 – 31

An examination of the means of the different age groups (e.g., middle school, high school, and college) revealed a curvilinear relationship between age and scores on the *Cyberbullying Survey*. Since age could not be entered into the simultaneous multiple regression, an ANOVA was also used to determine the influence of age on each dependent variable. Results of the ANOVA with respect to the effect of age are presented in Table 4.

ANOVA comparisons indicated that there is an overall effect of age on both cyberbullying and image cyberbullying. With regard to cyberbullying, posthoc t-tests showed that high school students cyberbullied significantly more than both middle school students and college-aged students, and that college-aged student cyberbullied significantly more than middle school students. Specific to image cyberbullying, posthoc t-tests revealed that high school student cyberbullied using an image significantly more than middle and college-aged students. No differences were observed between college and middle school students.

In the area of cybervictimization, a significant effect of age was observed upon overall cybervictimization, but not with regard to image cybervictimization. Posthoc t-tests indicated that high school students reported cybervictimization significantly more than middle school students and college-aged students, who did not differ from each other.

Study 2

Study two aimed to identify contextual variables that may be related to increased likelihood to perpetrate or be victimized by bullying and cyberbullying. Before the onset of the study, approval was obtained through the appropriate Institutional Review Board. Middle school students were asked to report on various family context variables, experiences with bullying, and experiences with cyberbullying. Two hundred twenty three students in the 6th, 7th, and 8th grades, ranging in ages from 11 to 14 years, participated via survey. The sample population was obtained from rural and suburban schools in the Midwest. According to self-report classifications, 52% of student respondents were Caucasian, 22% were African American, 5%

were Hispanic, 4.5% were Asian, and 12.5% reported another ethnicity. The responding population consisted of slightly more females than is typical of the population in general, 59.6% of respondents were female. Prior to the study, a consent form was completed by the participant's guardian, informing them of the purpose of this study. Additionally, participants were rewarded with Tootsie Rolls when completed consent forms were returned.

Survey packets were completed either during students' first hour class or during study hall. The first page of the survey packet was an assent form for the participants to read and sign. Directly following the assent form was the *Demographic Information and Access to Technology Survey*, then the *Cyber Bullying and Victimization Surveys*, and finally the *Family Assessment Survey*. Upon distribution of the survey packets, participants were instructed to read and follow all instructions carefully, take as much time as necessary, and complete the measures in their entirety. Participants were asked to report demographic information, which consisted of their gender, ethnicity, grade, and age. In addition, they reported on how often they used an instant messaging program, how many text messages they typically sent in a day, and how many hours they spent online. The *Cyberbullying Survey* was used to assess experiences with cyberbullying as in Study 1, with the exception that items about image cyberbullying and cybervictimization were not included. Cronbach's alpha within this study was in the good range at $\alpha=.82$ for the Cyberbullying Subscale and at $\alpha=.88$ for the Cybervictimization Subscale. A similar tool assessing traditional forms of bullying, the *Traditional Bullying and Victimization Survey*, was developed for this study. Each subscale contained nine items that were designed to assess the participants' experience with traditional bullying. The Traditional Bullying Subscale asked about participants' experience as perpetrators of bullying with the Traditional Victimization Subscale asked about experiences being victimized. For example, one item on the Victimization Subscale asked participants, "In the past year I have been beaten up (hit, kicked, and/or pushed) by someone." Each question was answered using a 5-point Likert scale on which 0 = Never, 1 = Rarely, 2 = Once a month, 3 = Once a week, 4 = Once a day, and 5 = Several times a day. Cronbach's alphas reflected internal consistency of the Bullying Subscale at $\alpha=.77$, and $\alpha=.87$ for the Victimization Subscale.

The *Family Assessment System* (Jewell & Stark, n.d.) is comprised of 60 questions designed to measure 12 areas of family life. For the purposes of this study, 30 questions were used and the following areas were examined relative to bullying: family cohesion, authoritarian parenting style, and family conflict. Participants answered each question with "Never true," "A little true," "Sometimes true," "Mostly true," and "Always true." Sample questions included "There is a feeling of togetherness in my family," "The punishment for breaking rules in my family is too strict," and "We fight in our family." The *Family Assessment System* also asks for information regarding which parental figures participants have lived with for the past five years. Eight-four percent of participants reported living with more than one parental figure, while 15% reported living with only one parental figure. According to interpretive guidelines provided by George and Mallery (2003), Cronbach's alphas for the various scales were in the good range $\alpha=.84$ for the cohesion scale, and in the questionable range for the authoritarian and conflict scales $\alpha=.62$ and $\alpha=.66$, respectively).

Few participants reported experience with cybervictimization and even fewer reported experience with cyberbullying; overall means for cyberbullying in this study appear to be lower than was observed in Study 1. Means and standard deviations for each subscale are reported in Table 5. A strong correlation was observed between cyberbullying and cybervictimization and

moderate correlations were observed between all other subscales. Intercorrelations between subscales are reported in Table 6.

Correlations between *Family Assessment System* variables (cohesion, authoritarian parenting style, and conflict) and survey responses regarding experiences with cyber and traditional bullying and victimization are presented in Table 7. Overall, family conflict had a significant positive relationship at the moderate level with both forms of bullying and both forms of victimization. Authoritarian parenting style had a significant positive relationship at the moderate level with reported levels of cyberbullying.

To understand which *Family Assessment System* variable best predicts traditional and cyberbullying and victimization, the exclusive relationships between each family variable and bullying and victimization behaviors were examined via simultaneous multiple regression. Number of family members living in the household was also entered to determine whether having one or two parents was related to bullying or victimization. Simultaneous regression was selected because there was not prior theoretical support for one predictor having more influence than another.

Table 6. Correlations observed between responses on Cyberbullying and Traditional subscales

Variable	Cyberbully	Cybervictim	Traditional Bully	Traditional Victim
Cyberbully	-	.70**	.59*	.47*
Cybervictim	-	-	.56**	.62**
Traditional Bully	-	-	-	.61**
Traditional Victim	-	-	-	-

CONCLUSION

Summary

Results of Study 1 suggest that most middle, high school, and college students are communicating via electronic means on a daily basis. Instant messaging is likely less popular than it once was, but remains one method through which students interact socially. Others include other online forms of communication (e.g., social networking) and sending text messages. In this study, nearly 85% of respondents indicated sending one or more text messages per day, while over 90% of students spent some time online every day.

The majority of participants in both studies reported very low scores on the *Cyberbullying Survey* and *Traditional Bullying and Victimization Survey*. In Study 2, very few participants reported engaging in cyberbullying; similar levels of cybervictimization were observed across both studies. Results of Study 1 indicate that image cyberbullying and cybervictimization are occurring so infrequently that it is difficult to predict. However, there were several predictors of importance observed in these studies. Age, gender, frequency of text messaging, and time spent online were all predictive of cyberbullying in Study 1. Study 2 provided additional insight into the phenomenon of cyberbullying with the finding that authoritarian parenting style predicts both traditional and cyberbullying. Thus, the avenues through which cyberbullying becomes manifest may be similar to those through which students become traditional bullies. Indeed, the high intercorrelations between all forms of bullying and victimization observed in Study 2 suggest that not only are students often bully-victims, but those same students who are bullying and being victimized in the “physical” world are engaging in the same “digital behaviors.”

Additionally, Study 1 provided important insight into the age at which students are most likely to engage in cyberbullying. High school students reported the most cyberbullying, followed by college-age students, who reported cyberbullying others more than middle school students did. This finding is similar to that observed by Smith, Mahdavi, Carvalho, Fisher, Russell, & Tippett (2008), who looked at middle school and high school students. They found that older students reported engaging in significantly more cyberbullying. Study 1 supplemented Smith et al.'s (2008) findings by demonstrating a drop in cyberbullying behaviors after high school. Additionally, the finding that males reported cyberbullying others more than females is in agreement with the findings of Dehue, Bolman, & Vollink (2008) and Li (2007). Like general cyberbullying, high school students reported engaging in more image cyberbullying than middle school or college students, but there were no significant differences between middle school and college students' reporting. Also similar to general cyberbullying, males and those who send text messages more frequently were more likely to engage in image cyberbullying.

The family context variables that were examined in Study 2 provide important insight into the background characteristics that may incline a student to engage in bullying and/or be victimized by bullying, in both electronic and traditional formats. Overall family conflict demonstrated a significant positive correlation with both forms of bullying, while cohesion demonstrated a negative relationship with both cyber and traditional bullying. However, when analyzed via multiple regression, parenting style (authoritarian) was the most influential variable predicting bullying behavior. These findings are consistent with previous research

concluding that adolescents are more likely to engage in traditional bullying if they experience excessive punishment and/or frequent discipline (Oliver, Oaks, & Hoover, 1994; Ybarra & Mitchell, 2004).

In the area of victimization, high school students were more likely to be victims of cyberbullying than middle school or college students, with no differences observed between middle school and college students. This finding seems a natural reflection of the finding that high school students are more likely to engage in cyberbullying, as bullying typically occurs between same-age/grade peers. While time spent online was not a predictor of cybervictimization in Study 1, time spent texting and instant messaging were predictors, indicating that increased use of electronic communication is associated with increased risk of victimization. Unlike previous research indicating that females are more likely to be cybervictims than males (Dehue et al., 2008; Li, 2007), Study 1 did not reveal any differences in likelihood of cybervictimization due to sex. However, Beran and Li conducted a study in 2005 that also did not reveal an effect of sex on cybervictimization. Thus, the results of research to date on gender differences with respect to cybervictimization are mixed. Further work is needed to identify other variables that may mediate the link between sex and cybervictimization.

Overall, text messaging was the strongest predictor of both cyberbullying and cybervictimization in Study 1. Study 2 revealed that the strongest predictor of bullying behavior via both cyber and traditional formats was authoritarian parenting, which was a stronger effect than conflict or the potentially ameliorating effects of family cohesion. Victimization, however, was most strongly predicted by family conflict in Study 2.

Implications and Future Directions

The findings of both studies provide important implications for practitioners looking to appropriately target bullying and cyberbullying intervention and prevention programs. Specifically, despite the emergence of bullying behavior in early adolescence, cyberbullying in particular is most likely to occur during the high school years. Given the preponderance of bullying prevention programs targeting late elementary and middle school students in recent years, it is likely that at least some of the participants in this study had previously been exposed to instruction in bullying and how to respond to it. However, since more high school age students than any other age group report engaging in and being victims of bullying, intervention programs should continue to focus on preventing and intervening with bullying at the high school level. Among the evidence-based programs reviewed earlier in the chapter, only the Success in Stages® program includes materials targeting bullying behavior at the high school level. Given the rate of maturation and change during the adolescent years, it is perhaps unsurprising that high school students may easily forget or stop using the strategies they may have learned earlier on in adolescence to prevent or stop bullying and cyberbullying. Furthermore, if the majority of interventions themselves only teach strategies that are appropriate for older children and early adolescents, then high school students may find themselves ill-equipped to handle increasingly complex and sometimes confusing social relationships that involve bullying. Addressing this need will require intervention procedures that are adept at helping high school students to recognize bullying when it is occurring,

proactively attempt to stop it, and resolve resulting conflicts or disruptions in social relationships that may follow instances of bullying.

Evidence regarding the predictors of bullying and cyberbullying should be used to identify and target students who are at the greatest risk of engaging in bullying or being victimized by bullying. While it appears that more high school students may benefit from bullying intervention efforts than may be currently receiving those programs, students who are male, engage in frequent electronic communication, and come from family backgrounds characterized by authoritarian parenting are even more likely to be perpetrators of bullying. Schools that administer questionnaires to ask about bullying could use this information to survey these factors as well. Given the variability in frequencies with which students sometimes report engaging in bullying, information regarding other risk factors may help school personnel to identify students who are in need of the most help. For example, a male student who reports engaging in cyberbullying, describes his parents as authoritarian, and who sends several dozen text messages a day may engage in more severe or chronic forms of cyberbullying than a male student who reports engaging in cyberbullying, but also describes his family as cohesive and sends text messages less than 20 times a day. Small group interventions may be more salient for the former student than the latter, and when resources are limited, focusing intervention efforts on the most severe offenders may result in the greatest impact for overall school climate. Conversely, knowledge of behaviors that predispose students for bullying and/or victimization, such as texting often or spending a lot of time online, may help service providers to target prevention efforts at younger students or those who do not yet report high levels of bullying or victimization.

The implications of these findings for work with family members are also important. While authoritarian parenting has been linked to many negative outcomes for youth for quite some time (e.g., Jewell, Krohn, Scott, Carlton, & Meinz, 2008), its link to bullying behavior is relatively new (Ybarra & Mitchell, 2004). Practitioners inside and outside of schools should attend to the impact of family environment on adolescents' behavior – this finding is probably particularly salient for community-based practitioners who have the opportunity to assess and target familial interactions. It may be that parents who are able to set firm limits but also to compromise when their child's well-being demands it are teaching and modeling important skills in self-regulation, seeking out social support, and maintaining positivity. Future avenues of research should examine whether learning those skills provides additional benefit in reducing bullying behaviors, which would further strengthen the link between skills gained via appropriate parenting and engagement in bullying. Meanwhile, practitioners who have the opportunity to directly address parenting style may wish to examine whether adolescents with authoritarian parents are engaging in bullying and, if so, provide additional skill instruction to both adolescents and their parents in the areas of effective communication and compromise in interpersonal relationships.

Family context also has important implications for victimization, especially in the area of conflict. Family conflict predicted victimization via both traditional and cyber routes in Study 2, suggesting that the experience of frequently witnessing conflict in the home environment may result in adolescents who are either more tolerant of receiving aggression from others and/or less skillful in effectively refuting and discouraging aggression from peers. Clearly, more research is needed to specify the exact pathways through which family conflict makes adolescents more vulnerable to bullying and cyberbullying. In light of other findings regarding age group and the protective effects of cohesion, high school students from homes with high

conflict are particularly likely to be bullied traditionally and via cyber mechanisms. Additionally, practitioners should attend to the amount of conflict present in a student's family when considering whether to involve a student in a targeted intervention group or when working individually with such an adolescent. Such youth may require additional skill instruction and opportunities to rehearse proactively responding to conflict and/or aggression in a way that de-escalates the aggressor and communicates a lack of tolerance for aggressive and/or disparaging comments and actions.

In addition to the directions mentioned above, future researchers should re-examine the findings of this study to determine that the links observed between sex, age, access to technology, and family context variables are meaningfully linked to traditional, cyber, and image-based cyber bullying and victimization with a variety of adolescent populations. Of particular interest in bullying research is the extent to which self-report measures of bullying and victimization accurately reflect adolescents' actual experiences at school and in digital communication. While research examining the efficacy of bullying prevention measures has attempted in vivo observations of actual school-based behavior (e.g., Low et al., 2010), research into prevalence and factors related to bullying typically relies on self-report questionnaires to measure the extent of bullying and/or cyberbullying within a population. Expanding upon the research base by conducting observations of adolescent behavior, in particular, is likely to provide researchers and practitioners with more meaningful methods of identifying and evaluating bullying within a particular context, such as a school. Additionally, with the appropriate consent, qualitative examination of the content of adolescents' messages to and from each other in digital realms could provide meaningful insight into the types of messages and forms of bullying that are most damaging to adolescents, and could be examined in terms of the factors described above.

Just as aggression and concerns about aggression dominate discussions of human behavior from preschool through adulthood, bullying and its related forms will likely continue to be an issue requiring attention and resources for years to come. However, the extent to which social aggression is normative should always be considered in light of the potentially devastating effects that bullying can have on adolescents' lives. Understanding the conditions through which bullying is more likely to occur and the variables that may predispose an adolescent to be victimized will help practitioners and researchers alike to identify, target, and implement effective interventions to ameliorate and minimize the extent to which bullying negative impacts students of all ages.

Chapter 62

**SCHOOL BASED BULLYING IN IRELAND –
A CAUSE FOR CONCERN?
A REVIEW OF RESEARCH FROM NORTHERN
IRELAND AND THE REPUBLIC OF IRELAND**

ABSTRACT

Both Northern Ireland and the Republic of Ireland have, over the last 20 years, changed dramatically in response to a range of economic, political and social factors. One area of continuing social concern within both countries is that of bully/victim problems among school pupils. The present aim was to provide a review of research on the prevalence and social-psychological correlates of bully/victim problems among school children within both countries. Data are presented from a total of 15 studies located in Northern Ireland and 13 studies located in the Republic of Ireland. The findings suggest that, across a range of samples, measures, and sub-types of bullying behaviours, bully/victim problems among school children continues to remain a problem in schools across Ireland. The social-psychological consequences are considerable.

INTRODUCTION

Bullying in schools is an international problem (see Smith & Morita, 1999). Smith et al., (1999) present a cross-national perspective on the nature, prevalence and correlation of school bullying that encompasses specific reviews from each of the Scandinavian countries (Finland: Björkqvist & Österman, 1999; Denmark: Dueholm, 1999; Norway: Olweus, 1999a; Sweden: Olweus, 1999b); the U.K. and Republic of Ireland (Ireland: Byrne, 1999; Scotland: Mellor, 1999; England & Wales: Smith, 1999), Latin countries (France: Fabre-Cornali, Emin, & Pain, 1999; Italy: Fonzi et al., 1999; Spain: Ortega & Mora-Merchan, 1999; Portugal: Tomás de Almeida, 1999), central Europe (Switzerland: Alsaker & Brunner, 1999; Poland: Janowski, 1999; The Netherlands: Junger-Tas, 1999; Germany: Lösel & Bliesener, 1999; Belgium: Vettenburg, 1999), North America (Canada: Harachi, Catalano, & Hawkins, 1999a; USA: Harachi, Catalano & Hawkins, 1999b), the Pacific Rim (Japan: Morita, Soeda, Soeda, & Taki, 1999; Australia: Rigby & Slee, 1999; Aotearoa/New Zealand: Sullivan, 1999), and the developing world (e.g., Palestine, South Africa: Ohsako, 1999). Subsequently, comparable reviews have been provided on Northern Ireland (Mc Guckin, in press; Mc Guckin & Lewis, 2003).

The aim of the present chapter is to build on the foundational work of Mc Guckin (in press) and Mc Guckin and Lewis (2003) on Northern Ireland and Byrne (1999) on Ireland, by providing a contemporary review of school bullying in both the Northern Ireland and the Republic of Ireland. No attempt was made to revisit the “contextual” description of these countries provided by Byrne (1999) and Mc Guckin and Lewis (2003), as it is argued that these original descriptions are still relevant. Instead, the chapter provides an exhaustive review of the nature, incidence, and correlates of bully/victim problems among school children in Northern Ireland and the Republic of Ireland.

BULLY/VICTIM PROBLEMS IN NORTHERN IRELAND

At present there have been 15 studies undertaken on school based bullying in Northern Ireland.

Large Scale Studies

To date, there have been three large-scale research studies funded by the Department of Education for Northern Ireland (DENI): (i) Collins, Mc Aleavy, and Adamson (2002, 2004), (ii) Livesey et al. (2007), and (iii) RSM McClure Watters (2011). The strength of these studies rests in their sampling methodology (representative samples of school children from 120 schools: 60 primary; 60 post-primary) and use of the “gold-standard” Olweus Bully/victim Questionnaire (Olweus, 1989, 1996), thus allowing for cross-national comparisons. Two central questions from Olweus’ questionnaire are of interest for comparison to previous research: “How often have you been bullied at school in the past couple of months?” and “How often have you taken part in bullying others at school in the past couple of months?”

Study 1. Bullying in Schools: A Northern Ireland Study (Collins et al., 2002, 2004)

The first of these studies (*Bullying in Schools: A Northern Ireland Study*: Collins et al., 2002, 2004) employed the Revised Olweus Bully/victim Questionnaire (1996), and found, among a sample of 1,079 primary school pupils, that 40.1% reported being bullied in the past couple of months. In relation to being a victim of bullying, 26% claimed that it happened “once or twice in the last couple of months”, 6% stated it happened “two or three times a month”, 5% reported that it was “about once a week”, and 4% experienced it “several times a week”. Among the post-primary school sample of 1,353, a lower rate of victimisation (30.2%) was reported by the pupils (20.3%: “once or twice”; 3.4%: “two or three times a month”; 3%: “about once a week”; and 3.5%: “several times a week”). Furthermore, in relation to experiencing bullying for several years, 5% of primary school pupils and 2% of post-primary school pupils reported that this was the case. With regard to bullying other pupils at school, whilst 24.9% of primary school pupils reported that they had participated in this behaviour (22%: “occasional”; 3%: “frequent”), a higher rate (29%) was reported by post-primary school pupils (26%: “occasional”; 3%: “frequent”). A further group of bully-victims were identified: 15% among the primary school pupils and 12% among the post-primary school pupils. Questionnaires were also completed by staff within the participating schools, in relation to attitudes to and awareness of bullying, school anti-bullying policies, and procedures and their training needs. From their analysis of both pupil and staff questionnaires, Collins et al. (2002, 2004) concluded that bullying was occurring in all schools, even in the best regulated ones, was not specific to age or gender, and at times it was underplayed by the schools and teachers.

Study 2. The Nature and Extent of Bullying in Schools in the North of Ireland (Livesey et al., 2007)

The second of these studies (*The Nature and Extent of Bullying in Schools in the North of Ireland*: Livesey et al., 2007) employed the Revised Olweus Bully/victim Questionnaire (Olweus, 1996), but with the addition of questions in relation to Section 75 of the *Northern Ireland Act 1998* (The Stationery Office, 2003) which related to opinions on equality in relation to ethnicity, religion, and disability. Among the primary school sample of 993 pupils, 43.3% reported that they were a victim of bullying in the past couple of months (26.2%: “once or twice”; 7.9%: “two or three times a month”; 4.3%: “about once a week”; 4.9%: “several times a week”). A lower rate of victimisation (28.8%) was reported among the 1,319 post-primary school pupils (21.1%: “once or twice”; 2.6%: “two or three times a month”; 2.3%: “about once a week”; 2.7%: “several times a week”). With regard to bullying other pupils, 22.1% of primary school pupils indicated they had done this (17.1%: “once or twice”; 2.7%: “two or three times a month”; 1.4%: “about once a month”; 0.9%: “several times a month”). One fifth (21.9%) of post-primary school pupils stated that they had participated in bullying other pupils over the past couple of months (19.1%: “once or twice”; 1.1%: “two or three times a month”; 0.9%: “about once a week”; 0.8%: “several times a month”). Pupils were also categorised to one of four categories: (i) not bully or victim, (ii) victim, (iii) bully, or (iv) bully-victim, based on their answers to the two key questions, as per Solberg and Olweus (2003) and Ahmed and

Braithwaite (2004). Among the primary school pupils, 80.4% were not involved in bullying and were classified as “not bully or victim”, 14.6% were categorised as a “victim”, 2.5% as a “bully” and 2.5% were considered “bully-victims”. In the post-primary sample, 90.3% were assigned as “not a bully or victim”, 6.9% were a “victim”, 2.1% were classified as a “bully” and 0.7% were categorised as a “bully-victim”.

Furthermore, in relation to cyberbullying, 12.9% of primary school pupils and 7% of post-primary school pupils reported being “bullied with the use of mobile phones”. In relation to being “bullied with the use of computers”, 7.4% of primary school pupils and 4.4% of post-primary school pupils stated that it had happened to them. In relation to bullying others, 3.4% of primary school pupils and 6.9% of post-primary school pupils admitted that they had done this using a mobile phone, and 2.1% of primary school pupils, and 4.6% post-primary school pupils stated that they used a computer to bully others.

Questions were also asked in relation to having a disability and being involved in bully/victim problems. In relation to having a disability, 16.3% of primary school pupils reported that they did have a disability. Livesey et al. (2007) reported that there was a significant association between whether a pupil had a disability and frequency of victimisation. When compared to their non-disabled peers (40.4%), a larger percentage (58.5%) of those with a disability reported that they were a victim of bullying behaviour. A significant association was also found in relation to bullying other pupils, with a greater percentage of pupils with a disability (37.7%) reporting that they had bullied other pupils in comparison to those without a disability (19.1%). Amongst the post-primary sample, 5.9% reported having a disability, with similar significant associations being found in relation to reporting of having a disability and being a victim of bullying behaviour: 29.7% of those with a disability reported being a victim in comparison to 27.7% for those with no disability. Similarly, significant associations were also reported for reporting of a disability and involvement in bullying others, with a greater percentage (35.4%) of pupils with a disability admitting bullying other pupils in comparison to those pupils (21.2%) with no disability.

In comparison to the findings of Collins et al. (2002, 2004) from 5 years previous, the rates of reported bullying behaviour by victims, bullies, and bully/victim were similar in nature. Livesey et al. (2007) concluded that schools still faced challenges in terms of creating an anti-bullying culture and preventing bully/victim problems among school pupils and protecting children who had experienced this problem.

Study 3. The Nature and Extent of Pupil Bullying in Schools in the North of Ireland (RSM McClure Watters, 2011)

The third funded project (*The Nature and Extent of Pupil Bullying in Schools in the North of Ireland*: RSM McClure Watters, 2011), built upon the strong methodological and empirical base set by the previous two projects. Similarly, it examined the nature and incidence of school bullying, but it also included questions relation to cyberbullying (like Livesey et al., 2007) and a survey of staff (like Collins et al., 2002, 2004). Questionnaires were completed by a representative sample of 904 primary pupils and 1,297 post-primary pupils, along with 58 primary teaching staff, 57 primary non-teaching staff, 56 post-primary teaching staff, and 58 post-primary non-teaching staff.

For consistency with the previous research, the Revised Olweus Bully/victim Questionnaire (1996) was utilised, with further questions asked in relation to cyberbullying, pupils' awareness of, and use of, available resources to help with dealing with incidents of bullying. As before, questions relating to Section 75 of the *Northern Ireland Act 1998* (The Stationary Office, 2003) on equal opportunity and good relations were also included (e.g., race or skin colour, disability, religion). Furthermore, in an extension to the previous research, one senior teaching member of staff who had specific responsibility for "pastoral care" and one non-teaching member of staff were interviewed in each school sampled.

Within the primary school sample, 39.3% (n = 352) of pupils had been victimised in the previous two months (22.1%, n = 198: "it has only happened once or twice"; 7.7%, n = 69: "2 or 3 times a month"; 4.6%, n = 41: "about once a week"; 4.9%, n = 44: "several times a week"), with 9.5% (n = 85) of these pupils experiencing bullying once a week or more often. Amongst post-primary school pupils, the rate of victimisation was 29.5% (n = 380: 18.4%, n = 238: "it has only happened once or twice"; 4.3%, n = 55: "2 or 3 times a month"; 3.3%, n = 42: "about once a week"; 3.5%, n = 45: "several times a week").

In response to the question about bullying others, 21.5% (n = 193) of primary school pupils admitted being involved in this behaviour (17.6%, n = 158: "it has happened only once or twice"; 2.2%, n = 20: "2 or 3 times a month"; 1.1%, n = 10: "about once a week"; 0.6%, n = 5: "several times a week"), and 1.7% (n = 15) of these pupils engaged in this behaviour once a week or more often. Among the post-primary school pupils, 17.8% (n = 230) reported that they did this "once or twice", and 3.4% (n = 44) reported that they bullied others on a more frequent basis (1.6%, n = 21: "2 or 3 times a month"; 1.1%, n = 14: "about once a week"; 0.7%, n = 9: "several times a week").

Similar to the previous iteration of the study (Livesey et al., 2007), pupils were categorised as "not a bully or victim", "victim", "bully", or "bully-victim" based on their answers to the two key questions. In relation to primary school pupils, 80.2% were classified as being "not a bully or victim", 15.8% as a "victim", 2.6% as a "bully", and 1.3% as a "bully-victim". Among the post-primary school pupils, 86.6% were categorised as being "not a bully or victim", 9.9% as a "victim", 2.3% as a "bully", and 1% as a "bully-victim" (Note: whilst percentage values were reported for these groups, the numbers of pupils in each category was not reported).

In relation to being a victim of cyberbullying, 15.5% (n = 140) of primary school pupils reported that they had experienced this in the past couple of months, with "I received a threatening message via IM, text, email" (6%, n = 54) and "I received a message that showed people were talking about me nastily online" (6.1%, n = 55) being most commonly reported. Similar trends were reported amongst the post-primary sample, with 17% (n = 221) reporting cyberbullying and "I received a threatening message via IM, text, email" (5.3%, n = 69) and "I received a message that showed people were talking about me nastily online" (5.5%, n = 71) being the most reported options. Text message (primary: 8.1%, n = 73; post-primary: 9.6%, n = 124) and social networking (primary: 5.9%, n = 53; post-primary: 10.6%, n = 138) were two methods of bullying most commonly reported by a victim, to bully them using a mobile phone or computer.

When answering the question about involvement in cyberbullying other pupils in the past couple of months, 5.2% (n = 47) reported that they had engaged in this behaviour. Similar to the victim focused question, the most frequent reported responses were: "I sent him or her a threatening message via IM, text, email" (1.7%, n = 15) and "I sent him or her a message that showed people were talking about him or her nastily online" (1.8%, n = 16). Similarly, 6.6%

(n = 85) of post-primary school pupils reported being a cyberbully, with “I sent him or her a message with insults calling him or her gay (whether true or not)” (2.1%, n = 27) and “I sent him or her a threatening message via IM, text, email” (1.9%, n = 25) the most common responses. Similarly, text message (primary: 3.4%, n = 31; post-primary: 2.7%, n = 35) and social networking (primary: 2.1%, n = 19; post-primary: 3.2%, n = 42) were the two methods most commonly reported by a bully.

Similar to Livesey et al. (2007), analysis was also conducted regarding the relationship between involvement in bully/victim problems and disability. Overall, 12.1% of primary school pupils and 6.2% of post-primary school pupils reported having a disability (Note: whilst percentage values were reported for these groups, the numbers of pupils in each category was not reported). Among the primary school pupils, a large percentage of those that reported having a disability also reported that they had been victimized (44.3%, n = 47) compared to their non-disabled peers (38.6%, n = 300). A similar trend was evident among the post-primary school pupils, with 44.9% (n = 35) of those with a disability reporting being bullied compared to 28.2% (n = 337) for those without a disability. Furthermore, a greater percentage of those primary school pupils who had a disability reported being involved in bullying other students (27.8%, n = 30) than those without a disability (20.8%, n = 162). Similarly, 29.1% (n = 23) of those in post-primary school with a disability reported that they had bullied other pupils compared with 20.5% (n = 245) for those without a disability.

As mentioned previously, staff surveys were also conducted. In relation to the incidence of bullying over the past “two or three years”, the majority of primary school teaching (60%, n = 35) and non-teaching staff (65%, n = 37) considered it to be “about the same”. Within the post-primary sample, the incidence was also considered to be “about the same” by teaching (54%, n = 30) and non-teaching staff (52%, n = 29). In relation to cyberbullying, 17 primary school teaching staff and 18 non-teaching staff stated that cyberbullying and problems with *Facebook* and phones were becoming more common. In the post-primary school setting, almost three quarters of teaching staff and one-third of non-teaching staff noted that cyberbullying was increasing.

In comparison to the two previous studies, the incidence rate in relation to victimisation and involvement in bullying others for primary school pupils and post-primary school pupils remained consistent, with only slight changes occurring. All three studies reported victimisation rates of approximately 40% among primary school pupils and 30% among post-primary school pupils, and participation in bullying others for both school groups of approximately 20%. Based on their research findings, RSM McClure Watters (2011) made some key recommendations, such as reminding schools to update their policies and involve parents and pupils, that DENI should provide guidance on the roles of staff in dealing with school bullying, and provide guidelines on addressing cyberbullying for schools.

Smaller Scale Studies

In addition to the three large-scale and methodologically robust studies (Collins et al., 2002, 2004; Livesey et al., 2007; RSM McClure Watters, 2011), there has been a number of smaller scale studies that have explored the nature, incidence, and correlates of involvement in bully/victim problems amongst school pupils in Northern Ireland (Callaghan & Joseph, 1995; Collins & Bell, 1996; Espey, Duffy, & Mc Guckin, under review; Mc Guckin & Crowley, in

press; Mc Guckin, Cummins, & Lewis, 2008, 2009, 2010a, 2010b; Mc Guckin & Lewis, 2006; Mc Guckin, Lewis, & Cummins, 2010; Purdy & Mc Guckin, 2011; Schubotz, 2010). However, unlike the DENI supported large scale studies reported above, there was no consensus among the authors of these smaller studies regarding methodological issues.

Study 4. Callaghan and Joseph (1995)

Callaghan and Joseph (1995) examined the relationship between victimization and mental health among a sample of 120 10-12 year old pupils at two post-primary schools in Northern Ireland. The 18-item Birlson Depression Questionnaire (BDQ: Birlson, 1981), the Self-Perception Profile for Children (SPPC: Harter, 1985), and the Peer Victimization Scale (PVS: Neary & Joseph, 1994), and one standalone question ("Are there any children who are bullied in the classroom?") were completed by the pupils. In response to the standalone question, pupils were also asked to list the names of those children who they thought were being bullied and to include their own name if it was appropriate. Seventy pupils (58.33%) including 13 (10.83%) self-reported victims were identified by at least one of the pupils as being a victim. In relation to scores on the PVS (Neary & Joseph, 1994) and the BDQ (Birlson, 1981), the 70 peer-nominated victims had significantly higher scores than those that were not identified as victims by their peers. In relation to the SPPC (Harter, 1985), this group also had significantly lower scores than non-victims on the Social Acceptance sub-scale, the Behavioural Conduct sub-scale and the Global Self-worth sub-scale. This trend was similar for the self-reported victims, with this group having significantly higher scores on the PVS (Neary & Joseph, 1994) and the BDQ (Birlson, 1981), and significantly lower scores on the Social Acceptance and the Global Self-worth sub-scales of the SPPC (Harter, 1985) than those not identified as victims.

Study 5. Collins and Bell (1996)

Collins and Bell (1996) also utilised the SPPC (Harter, 1985) but assessed bully/victim problems by employing the Olweus Bully/victim Questionnaire (BVQ: Olweus, 1989) among a sample of 118 8-10 year old pupils from three Belfast primary schools. They also assessed aggressive-disruptive behaviour using the Revised Class Play Method (Masten, Morison, & Pellegrini, 1985). Nearly one-quarter (24%) were reported as bullies. However, similar data were not reported for victims, bully/victims, or bystanders. Significant positive associations were found between self-reports of bullying and peer-nominations of these bullies on the Revised Class Play Method (Masten et al., 1985). In relation to the SPPC (Harter, 1985), bullies scored significantly higher on all sub-scales, except for the Behavioural Conduct and Self-competence sub-scales than everyone else. It was also reported that bullies' scores were lower on the Behavioural Conduct sub-scale than victims and bystanders. Also, victims had lower levels of self-esteem on all sub-scales of the SPPC (Harter, 1985).

An Agenda for Change (Mc Guckin & Lewis, 2003)

These previous two studies (Callaghan & Joseph, 1995; Collins & Bell, 1996) were relatively small in nature and employed different means to assess bully/victim problems among

school pupils. In attempts to overcome the sporadic nature of research exploring such issues among school pupils in Northern Ireland, Mc Guckin, Lewis, and colleagues have been working in earnest to bring theoretical and methodological consensus to the area (Mc Guckin & Lewis, 2003). For example, the review of the following studies demonstrates how the team have been working with other researchers and agencies to improve the quality and consistency of the questions posed in large-scale studies among the Northern Irish school pupils. The outcome of this work has been that a consensus has now been reached whereby all future research exploring bully/victim problems should be comparable, not only with the DENI supported research, but also (and importantly), be comparable with the international literature on the issue.

Study 6. Mc Guckin and Lewis (2006)

The first of these (Mc Guckin & Lewis, 2006) reported upon a sample of 397 12- 17 year olds across Northern Ireland who were involved in the 1998 iteration of the Young Life and Times Survey (YLTS). The YLTS is administered by ARK, the Northern Ireland Social and Political Archive - managed jointly by the University of Ulster and Queen's University Belfast (www.ark.ac.uk/ylt). A victimisation rate of 76.8% was recorded from responses to the question 'Would you say that students at your school get bullied by other students?' A further five questions were posed to the pupils with regard to young people's experiences of bullying behaviour and being a victim of bullying, school policies on bullying, and the staff helpfulness in relation to bully/victim problems. Mc Guckin and Lewis (2006) concluded from the responses to these questions, that although schools were mainly proactive in the management of bully/victim problems, the rate of help-seeking behaviour amongst students was low.

Study 7. Mc Guckin, Cummins, and Lewis (2008)

Similar analyses of a different Province-wide survey were reported by Mc Guckin, Cummins, and Lewis (2008): the Young People's Behaviour and Attitudes Survey (YPBAS: Northern Ireland Statistics and Research Agency, 2000). Among a representative sample of 6,297 11 to 16 year olds in Northern Ireland, a victimisation rate of 43.3% ($n = 2,470$) was reported from answers to the question "Have you ever been a victim of the following – Being bullied?" Responses linked to bully/victim problems emerged in other areas of the survey, such as personal experiences of school meal-times, sporting activities and perceptions of personal safety. As previously, whilst the sampling procedures employed were robust, little was gained in terms of comparable knowledge about the nature, incidence, or correlates of involvement in bully/victim problems.

Study 8. Mc Guckin, Cummins, and Lewis (2009)

Mc Guckin, Cummins, and Lewis (2009) reported findings from the 2003 version of the YPBAS (NISRA, 2003), on three key questions relating to bully/victim problems ($N = 7,223$ 11 to 16 year olds). Self-reports of being a victim of bullying was admitted by almost one-fifth (17.2%, $n = 1,026$) of the sample, and 8.1% ($n = 492$) admitted that they had "picked on" or

bullied another pupil. The victimisation rate recorded was lower than that of the previous iteration (i.e., in 2000). Similar to the 2000 version of the survey, bully/victim problems emerged as a factor in personal experiences of school meal-times, sporting activities, and perceptions of personal safety.

Study 9. Mc Guckin, Lewis, and Cummins (2010)

Mc Guckin, Lewis, and Cummins (2010) analysed data from the 2004 iteration of the YLTS. Among a sample of 824 16 year olds a rate of victimisation of 13% (n = 107) was recorded from responses (frequency = “sometimes or more often”) to the statement “I was bullied at school”. This victimisation rate was lower than that reported by Mc Guckin and Lewis (2006). This version of the survey also included questions in relation to stress and the 12-item General Health Questionnaire (GHQ-12: Goldberg & Williams, 1988) was included to assess psychological health and general well-being. In relation to answers relating to stress and scores on the GHQ-12, 65.7% (n = 541) reported being stressed, and 23.8% (n = 189) had scores that were considered high enough on the GHQ-12 to be a “case” (utilising a cut-off score of 4: Mc Whirter, 2004). Furthermore, involvement in bullying behaviour was significantly related to increased stress and impairment in psychological well-being.

Study 10. Mc Guckin, Cummins, and Lewis (2010a)

Mc Guckin, Cummins, and Lewis (2010a) analysed the 2005 YLTS (N = 819 16 years old pupils). A victimisation rate of 30.5% (n = 244) was reported - higher than the previous version of the survey. Similar to the previous version of the YLTS, 64.7% (n = 522) reported being stressed and 21.4% (n = 172) had scores on the GHQ-12 (Goldberg & Williams, 1988) that were high enough to require psychiatric referral (utilising a cut-off of 4: Mc Whirter, 2004). Again involvement in bullying behaviour was significantly related to stress and impaired mental health.

Study 11. Schubotz (2010)

Schubotz (2010), in the analysis of the 2008 YLTS reported a victimisation rate of 37% from a sample of 941 16 year old pupils. From the GHQ-12 (Goldberg & Williams, 1998), 29% were within the “at-risk” group of a psychiatric disorder and answered questions relating to stress, where 39% reported that they were stressed often or very often. This version of the survey was expanded with the inclusion of questions on mental health and self-harm. Fifteen percent of pupils reported that they had thought seriously about self-harm and 10% had self-harmed (5%: once; 5%: more than once). Those pupils who had experienced bully/victim problems reported higher levels of stress than those that had not been involved in such problems. Furthermore, involvement in bully/victim problems was also related to mental and emotional health problems and self-harm, with 65% of those who had self-harmed reporting that they had been bullied at school. This was the first year of the presentation of questions

relating to self-harm, and the rate of bullying and self-harm are a cause for concern. Furthermore, as the YLTS has progressed through the years, the questions being asked are becoming more streamlined in line with international and national research, allowing for cross-national comparison.

Study 12. Mc Guckin, Cummins, and Lewis (2010b)

Mc Guckin, Cummins, and Lewis (2010b) examined the experiences of 11 year olds in Northern Ireland as recorded by the first two administrations of the annual Kids Life and Times Survey - the children's version of the YLTS (KLTS: 2008 [N = 3,440], 2009 [N= 3,699]). The surveys explored both traditional / face-to-face (f2f) and cyberbullying, along with the KIDSCREEN (Ravens-Sieberer et al., 2005; The KIDSCREEN Group Europe, 2006) to assess psychological well-being, and a World Health Organisation measure of family financial circumstances. The 2009 version also included further questions relating to Internet usage, Internet access, and appearance. In 2008, 22% (n = 750) of children reported being *physically* bullied at school either "a little" or "a lot", 38.8% (n = 1,328) reported they had been bullied *in other ways*, either "a little" or "a lot", and 10.3% (n = 353) reported that "yes" they had "been bullied by someone sending nasty texts or putting up bad things about you on the Internet". In relation to bullying others in a physical manner, 7.8% (n = 265) reported they had done this "a little" or "a lot", 12.8% (n = 437) admitted to "bullying children in other ways at school" either "a little" or "a lot", and 3.4% (n = 115) admitted that they had "taken part in bullying someone by sending nasty texts or putting up bad things about them on the Internet". A similar set of results were found in the 2009 survey, with 21.8% (n = 793) of children reporting being physically bullied at school either "a little" or "a lot", 36.2% (n = 1,311) being bullied in other ways either "a little" or "a lot", and 12.9% (n = 470) "been bullied by someone sending nasty texts or putting up bad things about you on the Internet". In relation to bullying others in a physical manner, 8.5% (n = 307) reported they had done this "a little" or "a lot", 13.1% (n = 476) admitted to "bullying children in other ways at school" either "a little" or "a lot". The question relating to cyberbullying other children was not, unfortunately, asked in the 2009 survey. Furthermore, across both years of the survey, involvement in bully/victim problems were associated with impaired psychological well-being.

As becomes evident through each iteration of these large and representative surveys, the key questions relating to experience of involvement in bully/victim problems, including cyberbullying and disablist bullying, reflect the influence and intervention of the present authors. Through their analyses and discussion of the datasets and methodologies employed, basic – but important – methodological issues have been addressed in subsequent surveys, leading to the collection and possible analysis and interpretation of new data to previous work in Northern Ireland and beyond. Thus, survey content regarding personal involvement (or not), and associated issues (e.g., health and well-being, help seeking) is now theoretically and methodologically much more robust.

Study 13. The Northern Ireland Anti-Bullying Forum (2007)

The Northern Ireland Anti-Bullying Forum (2007) explored cyberbullying in Northern Ireland using the Olweus derived questionnaire developed by Smith, Mahdavi, Carvalho, and Tippett (2006) among a sample 163 11-18 year old pupils in one post-primary school. The traditional / f2f victimisation rate was 14% (n = 22; 10%, n = 16: “once or twice”; 2%, n = 3: “2 or 3 times a month”; 2%, n = 3: “several times a week”) and the rate of experiencing cyberbullying was 8% (n = 13; 7%, n = 11: “once or twice”; 1%, n = 2: “about once a week”). These rates of victimisation are similar to the previous studies mentioned.

Study 14. Espey, Duffy, and Mc Guckin (Under Review)

Espey, Duffy, and Mc Guckin (under review) also assessed involvement in cyberbullying by utilising Smith et al.’s (2006) questionnaire among 757 Year 8 and Year 11 pupils in Northern Ireland. In relation to cyberbullying, a rate of involvement of 19.3% was reported, with 11.9% categorised as victims, 3.1% as bullies, and 4.3% as bully-victims. Traditional / f2f had a rate of involvement of 52.1%, with 31.6% of the sample classified as victims, 6.8% as bullies, and 13.7% as bully-victims. In terms of cyberbullying, the most common form was via text message, with videos via mobile phones being perceived as the form with most amount of harm associated with it. Also, over one-quarter of cyber victims reported that they did not know their cyberbully(ies). In terms of the best coping strategy, blocking the messages or telephone numbers was recommended by the pupils. In comparison to previous research, these rates of victimisation are a cause for concern.

Study 15. Purdy and Mc Guckin (2011)

Previously, it was highlighted within the DENI supported research of Livesey et al. (2007) and RSM McClure Watters (2011) that bullying in relation to a disability (i.e., disablist bullying) is becoming more prevalent – perhaps due to a more inclusive society and school system, with disabled and non-disabled pupils studying side-by-side. In a rare study encompassing samples from both Northern Ireland and the Republic of Ireland (supported by the Standing Conference on Teacher Education North and South: SCoTENS), Purdy and Mc Guckin (2011) examined trainee teachers’ knowledge of, and confidence with, dealing with (i) traditional / f2f bullying, (ii) Special Education Needs (SEN), and (iii) the nexus of these two areas - disablist bullying. The results of their study highlighted that although trainee teachers placed high importance on the need to understand and respond proactively to issues relating to bullying and SEN, their confidence in relation to both was low and they had not received any training in relation to disablist bullying. Furthermore, 35.3% of the sample reported that they would revert to “natural instinct” if they had to deal with an incident of disablist bullying.

Utilising a similar methodological approach, and supported by SCoTENS, Purdy and Mc Guckin (in press) have explored teachers’ (Northern Ireland and Republic of Ireland) knowledge of the legal issues regarding cyberbullying. The research was designed to produce clear guidance to schools on their legal responsibilities regarding cyberbullying through the

publication and dissemination of a teacher-friendly pamphlet and increased knowledge and confidence regarding cyberbullying and legal remedies for the phenomenon.

Conclusion

Until recently, much of the research in Northern Ireland that has explored school bullying has been sporadic in nature, focusing on the incidence, nature, and correlates of bully/victim problems. Evident among these studies was a lack of methodological agreement in terms of definition, the time-reference period for the bullying to have occurred (e.g., previous week, previous two months, previous year) and whether the methodologies utilised (e.g., interview, questionnaire) allowed for comparison to the international literature. In addition, there is inconsistency in the reporting of findings, with some researchers reporting in percentages, some in numbers, and others choosing to categorise the respondents.

BULLY/VICTIM PROBLEMS IN REPUBLIC OF IRELAND

Research efforts regarding bully/victim problems in the Republic of Ireland have been influenced by the internationally recognised work of O'Moore and colleagues at the Anti-Bullying Centre in Trinity College Dublin. Indeed, O'Moore's Anti-Bullying Centre has been at the centre of much of the applied research regarding bully/victim problems across the lifespan and in schools, the workplace, and community settings in the Republic of Ireland and internationally.

At present there have been 13 studies undertaken on school based bullying in the Republic of Ireland.

Study 1. Byrne (1987)

The first key study on the nature of bully/victim problems in Ireland was conducted by Byrne (1987). Among a sample of 323 12-16 year old post-primary school boys, 5.2% were identified as victims and 4.9% were involved as bullies. Furthermore, among pupils in remedial classes, 13.7% were categorised as a victim and 9.1% as a bully. These rates were based on teacher ratings, so it is a possibility that the incidence rates may be underestimated. This was highlighted by O'Moore and Hillery (1991) where teachers nominated those that were involved in bullying behaviour. They identified 22% pure bullies (never been bullied) and 25% bully-victims. They reported that teachers did not identify a quarter of the total number of bullies present in the sample. They also reported that bullies and victims experienced lower levels of self-esteem (as measured by the Piers-Harris Self-Concept Scale: Piers, 1984) in comparison to those not involved in bully/victim problems.

Study 2. O'Moore and Hillery (1989)

O'Moore and Hillery (1989), among a representative sample of 783 seven to thirteen year old primary school pupils in Dublin, utilised Roland and Munthe's (1989) 14-item self-report questionnaire. A victimisation rate of 63% (n = 493) was reported with 54.9% (n = 430) reporting that it happened occasionally and 8% (n = 63) of these reporting that they had been bullied on a frequent level ("once a week" or "more often"). In relation to the current school term, 34.4% were bullied occasionally during that term and 7.7% were bullied frequently. In relation to bullying others, 56% (n = 359) admitted to doing this, 43.3% of these did so occasionally ("once or twice" or "sometimes") and 2.5% bullied "seriously" ("once a week" or "more often"). In relation to bullying in the current school term, 27.4% reported bullying others occasionally and 1.8% (n = 14) did so to a serious level. Of those respondents that were bullied occasionally during the term (55%: "once or twice" or "sometimes"), 42.8% (n = 115) reported that they had also bullied others occasionally, and 3.3% (n = 9) had bullied others frequently. Of those that had been bullied frequently during the term, 40% (n = 24) had bullied others occasionally and 5% (n = 3) had bullied others on a frequent level. Furthermore, 109 of the sample attended remedial classes and 67.9% of these reported being a victim of bullying and 54.3% reported participated in bullying others.

Study 3. Byrne (1994)

Byrne (1994), among a sample of 1,302 primary and post-primary school pupils and 44 teachers (primary and post-primary) explored the incidence of bully/victim problems through teacher- and peer-ratings, class questionnaires, and interviews. Ten per-cent (10.4%) of the total sample reported being involved in bully/victim problems as either a bully (5.3%) or as a victim (5.1%). Furthermore, similar to O'Moore and Hillery (1991), when compared to those not involved in bully/victim problems, bullies and victims reported lower levels of self-worth. Bullies also reported higher levels of aggression, hostility, and a domineering nature towards their peers along with low levels of anxiety and insecurity. Conversely, victims reported higher levels of depression, worry, fear of new situations, and a withdrawn nature. In relation to early school completion, bullies showed the highest rate of 36.6% in comparison to 13.8% for victims. In addition, whilst 80.5% of teachers rated bullying as a major problem in schools, only 39% reported it as a large problem in their school. Moreover, just 5% of teachers felt that their teacher training prepared them to deal with bullying in schools.

Study 4. O'Moore, Kirkham, and Smith (1997)

A nationwide study of bully/victim problems in primary and post-primary schools in Ireland was conducted in 1993 by O'Moore, Kirkham, and Smith (1997), utilising a modified version of the Olweus Bully/victim Questionnaire (Olweus, 1989; Whitney & Smith, 1993) among a sample of 20,442 pupils. In relation to being a victim of bullying, 31.3% (n = 3,064) of primary school pupils (18.6%, n = 1,777: "once or twice"; 8.4%, n = 807: "sometimes"; 1.9%: "once a week"; 2.4%: "several times a week" [n = 480 for these last two combined]) and 15.6% of post-primary pupils, reported that they had been a victim of bully/victim problems

within the last term (10.8%, $n = 1,172$: “once or twice”; 2.9%, $n = 316$: “sometimes”; 0.7%: “once a week”; 1.2%: “several times a week” [$n = 207$ for these last two combined]). In relation to bullying others, 26.4% ($n = 2,524$) of primary school pupils (20%, $n = 1,904$: “once or twice”; 5.1%, $n = 482$: “sometimes”; 0.7%: “once a week”; 0.7%: “several times a week” [$n = 138$ for these last two combined]) and 14.9% ($n = 1,606$) of post-primary school pupils reported that they had been involved with bullying others in school within the last term (11.5%, $n = 1,239$: “once or twice”; 2.4%, $n = 264$: “sometimes”; 0.3%: “once a week”; 0.7%: “several times a week” [$n = 103$ for these last two combined]). Pupils were further categorised as pure bullies, pure victims, and bully-victims. Among the primary school sample, 12.3% were categorised as pure bullies, 17.1% as pure victims, and 14.1% as bully-victims. In the post-primary sample, the percentages for each of the categories were lower, with 10.8% classified as pure bullies, 11.5% as pure victims and 4.1% as bully-victims. (Note: whilst percentage values were reported for these groups, the numbers of pupils in each category was not reported).

Study 5. O’Moore and Kirkham (2001)

In a follow up study in 1994, O’Moore and Kirkham (2001) examined the relationship between self-esteem and bullying behaviour among a sample of 8,429 eight to eighteen year old pupils (primary and post-primary) who completed a modified version of the Olweus Bully/victim Questionnaire (Olweus, 1989; Whitney & Smith, 1993) and the Piers-Harris Self-Concept Scale (Piers, 1984). Those pupils that were involved as a bully, as a victim, or both had lower levels of Global Self-worth than those not involved in bullying behaviour. For victims, as the frequency of victimisation increased, levels of self-esteem decreased. Also, on the different dimensions of the Piers Harris Self-Concept Scale (Piers, 1984), they rated themselves with significantly higher scores on Behaviour and Anxiety, and significantly lower scores on Popularity, Physical Appearance, and Intellectual and School Status in comparison to those that had not been bullied. However, they had significantly higher levels of Global Self-worth than bully-victims. Among those primary school pupils that were categorised as pure bullies and bullied on the most frequent level, they reported significantly lower scores on the dimensions of Behaviour, Intellectual and School Status, Physical Appearance, Anxiety, Popularity, and Happiness and Satisfaction than those that did not bully. Furthermore, post-primary school bullies rated themselves with significantly lower scores on Behaviour, Intellectual and School Status, Popularity, and Happiness and Satisfaction. O’Moore and Kirkham (2001) found, across both primary and post-primary pupils that compared with pure bullies, bully-victims that bullied moderately and frequently and were bullied moderately and frequently, reported significantly lower levels of Global Self-worth, with lower scores of Behaviour, Intellectual and School Status, Physical Appearance, Popularity, and Happiness and Satisfaction, but higher scores of Anxiety.

Study 6. Guerin and Hennessy (2001)

Guerin and Hennessy (2001), among a sample of 940 primary school pupils in fifth and sixth class, utilised a questionnaire designed by the researchers to measure the nature and incidence of bully/victim problems in schools. The questionnaire posed questions related to

pupil's experiences of school, their involvement in bullying, and their attitudes to, and definitions of, bullying. The focus of the research was on the involvement in bully/victim problems. Involvement in bully/victim problems was reported by 31.2% ($n = 293$) of the sample, with 15.6% ($n = 147$) being classified as a victim, 6.1% ($n = 57$) as a bully, and 9.5% ($n = 89$) as a bully-victim.

Study 7. Connolly and O'Moore (2003)

Connolly and O'Moore (2003) examined the role of personality and family relations in bullies, utilising The Eysenck Personality Questionnaire Junior (Eysenck & Eysenck, 1975) and the Family Relations Test (Bene & Anthony, 1957) to assess the direction and intensity of the young person's feelings towards each of their family members and their estimation of the reciprocal feelings towards them. The sample consisted of 228 six to sixteen year olds, with 115 categorised as bullies and 113 as "controls". Categorisation as a bully or a control was based on a modified version of the Bankside Boys' School and Lamont Girls' Schools Questionnaire (Keise, 1992). In relation to personality, bullies scored higher in terms of Extraversion, Psychoticism, and Neuroticism in comparison to the controls. In relation to family relations, bullies reported higher scores in terms of emotional inhibition and had assigned significantly more negative statements to themselves compared to the controls. They also reported ambivalent relationships with their siblings and both parents whereas the controls portrayed positive relationships with their family members. Based on these findings Connolly and O'Moore (2003) recommend early identification of bullies and the involvement of their family in the intervention.

Study 8. James, Sofroniou, and Lawlor (2003)

James, Sofroniou, and Lawlor (2003), among a sample of 1,068 post-primary school second year pupils utilised a modified version of the Olweus Bully/victim Questionnaire (Olweus, 1993). Pupils were selected from participating schools in the "Cool School Programme" (an anti-bullying programme). Data were also collected in relation to the emotional reaction to being bullied (e.g., feeling sad, angry, isolated, afraid, fed up, depressed, suicidal, humiliated, hopeless, insecure, unsure of themselves, and afraid of school). These items represented experienced emotions of young people that attended a Child Psychiatry Clinic. In relation to being a victim, 15% ($n = 169$) of pupils reported that they were a victim. Some cases of these were excluded from analysis due to missing data (gender, type of bullying, emotions response) which lowered the percentage of victims with full data to 11% ($n = 120$; 5.6%: "once or twice"; 2.4%: "once a week or more"; 3.1%: "several times"). In relation to the type of bullying reported, name-calling was more frequently reported followed by having rumours spread about them, being threatened, and then being physically hurt. Following factor analysis on the various items relating to emotional response, two key factors emerged: Sadness-Anxiety and Anger-Frustration. In relation to these two factors, as the frequency of bullying increased, so did the victim's feelings on the sadness and anxiety factor, and victims reported feelings of anger/frustration irrespective of the frequency of the bullying behaviour. Those victims who reported that rumours were spread about them reported significantly higher scores

on both factors of emotional response. Those victims who reported that no one talked to them (exclusion) reported significantly higher scores on the sadness-anxiety factor. Suicidal feelings due to bullying were reported by 21% of victims.

Study 9. Mills, Guerin, Lynch, Daly, and Fitzpatrick (2004)

Mills, Guerin, Lynch, Daly, and Fitzpatrick (2004) report on data collected as part of a larger piece of research (Lynch, Mills, Daly, & Fitzpatrick, 2004) that investigated the prevalence of psychiatric disorders in a community setting sample of young people, aged between 12-15 years, and located in eight secondary schools in North Dublin. After a screening process involving the use of the Strengths and Difficulties Questionnaire (Goodman, 1997) and the Children's Depression Inventory (Kovacs, 1985, 1992), the final sample for analysis were the 209 (97 male, 112 female) students who presented for interview post-screening. The post-screening interview involved the use of the Schedule for Affective Disorders and Schizophrenia for School Aged Children Present and Life Time Version (KSADS-PL: Kaufman, Birmaher, Brent, Rao, & Ryan, 1996, 1997), the Scale for Suicide Ideation (SSI: Beck, Kovacs, & Weissmann, 1979), and the Suicide Intent Scale (SIS: Beck, Schuyler, & Herman, 1974) where required. Within the KSADS-PL, respondents were asked if they had ever experienced being bullied by their peers. The researchers had no predetermined criteria for what constituted an episode of bullying, instead relying on the respondent's own descriptions of experiences that they considered to be bullying. The victimisation rate was 34.5% ($n = 72$), with three quarters of these ($n = 54$) reported previous victimisation, and the remainder ($n = 18$) reporting that they were currently being bullied. Being a victim was associated with depression (past episodes and not current depressive episodes), suicide ideation, and more likely to have attempted suicide, and more likely to be referred to psychiatric services. Against expectations, victimization was not associated with anxiety or previous behaviour problems.

Study 10. O'Moore and Minton (2005)

O'Moore and Minton's (2005) work related to the effectiveness of an anti-bullying programme across 22 primary schools, using a modified version of the Olweus Bully/victim Questionnaire (Olweus, 1989; Whitney & Smith, 1993), before and after the programme. Questionnaires were completed by 525 third and fourth class pupils in 1998-1999 prior to the implementation of the anti-bullying programme to establish the rate of bullying behaviour in the schools. One year after the programme had been implemented, questionnaires were distributed again to the same students who were then in fourth and fifth class, yielding a sample of 520. Teachers also completed questionnaires (Rigby, 1997) at the two time points regarding their knowledge and feelings regarding bullying. Results highlighted that prior to the implementation of the anti-bullying programme, 36.7% of respondents were categorised as victims and 27.1% of pupils were classified as bullies. Following the implementation of the anti-bullying programme, the percentage of victims fell to 29.5% and the percentage of bullies dropped to 22.4%. This reduction in the percentage of victims and bullies was significant in nature, thus highlighting the effectiveness of the anti-bullying programme. (See Farrington &

Ttofi, 2009 for a scholarly review of the efficacy of this and noteworthy intervention / prevention programmes from across the world.)

Study 11. James et al. (2006)

Similarly, James et al. (2006) examined the experiences of staff and students of one school's participation in an anti-bullying programme (the "Cool School Programme": CSP) and impact of the programme. The sample consisted of 174, 13-17 year old pupils and 32 teachers. Students were administered a non-standardized questionnaire devised by the CSP team. The questionnaire focused on: (i) teacher ability to manage bullying, (ii) telling a teacher if you experience bullying, (iii) safety in school, (iv) has the CSP made a difference?, and (v) were there any changes since CSP started? Answers were collapsed, where possible, into themes. The findings were that 91% (n = 159) of the students felt that teachers took bully/victim problems seriously, 89% (n = 155) reported that they thought that the teachers knew how to deal with bullying, and 75% (n = 131) thought that they would be able to tell a teacher if they were bullied. Furthermore, 87% (n = 151) reported that their class had a better atmosphere and 93% (n = 162) felt safe at school. In relation to teachers, 72% (n = 23) felt a greater confidence in their abilities to deal with bullying, 84% (n = 27) reported that they were more vigilant, 94% (n = 30) thought students felt safer at school, and 69% (n = 22) thought it the atmosphere was better in the school. The majority (94%, n = 30) reported that they felt the programme had become part of the schools culture and that it would continue (97%, n = 31). James et al. (2006) highlight the need for anti-bullying programmes to focus on helping and supporting victims of bullying, to empower bystanders to intervene and work with those involved, along with reporting of bullying. They also advocate that staff, students and parents should work together to manage this on-going problem in schools.

Study 12. Minton and O'Moore (2008)

Minton and O'Moore (2008), in their 2004-2005 "ABC" study, utilised a modified version of the Olweus Bully/victim Questionnaire (Olweus, 1989) among a sample of 2,312 8 to 12 year old primary school pupils across 33 primary schools and 3,257 12 to 16 year old pupils across 12 post-primary schools. Almost one-third (29.2%) of primary school pupils reported that they had been bullied (22.7%: "once or twice" or "sometimes"; 3.4%: "once a week"; 3.1%: "several times a week") and 22.9% of post-primary students reported that they were a victim of bullying (18%: "once or twice" or "sometimes"; 2.8%: "once a week"; 2.1%: "several times a week"). Pupils were also "categorized" based on their answers. Amongst the primary school pupils, 21.2% were involved as a victim only, 6.8% were involved as a bully only, and 7.3% were involved as a bully-victim. With regard to post-primary school pupils, 15.2% were involved as a victim only, 13.5% were involved as a bully only, and 7.7% were involved as a bully-victim. This was a rate of involvement of 35.3% for the primary school sample and 36.4% for the post-primary school sample. Whilst the rates reflected a decrease in the primary school sample when compared to the 1993 nationwide survey (O'Moore et al., 1997), there was an increase for the primary school sample. Minton and O'Moore (2008) reported that the primary school pupils were overall significantly less likely to report that they were involved in

bully/victim problems and that they had bullied others, but they were significantly more likely to be a “pure victim”. Furthermore, pupils from post-primary schools were overall significantly more likely to be involved in bully/victim problems, and to be classified as a “pure bully”, “pure victim”, and “bully-victim” than their counterparts in the 1993 nationwide study (O’Moore et al., 1997).

Study 13. Sentenac et al. (2011)

Sentenac et al. (2011) explored bullying behaviour among 12,048 students aged 11, 13, and 15 years, who had a disability or chronic illness (D/CI) in Ireland and France, as part of a cross-national study: 2006 Health Behaviour in School-aged Children. Within the survey, bullying was assessed through questions from the Olweus Bully/victim Questionnaire (1993). Other questions were also asked in relation to family affluence (the Family Affluence Scale: Currie et al., 2008), quality of social network on the communication with same-gender friends and social support from classmates, and family factors through family structure and communication with parents. Questions were also asked to identify if the student had a disability. Respondents were categorised as non D/CI children, D/CI without restriction in participation, and D/CI with restriction in participation. Restriction referred to where children had a D/CI that restricted their participation or attendance at school. In relation to having a D/CI, Ireland had a significantly higher rate of 20.6%, than that of France (16.6%), whereas France reported a higher incidence of bullying (34.2%) than Ireland (25.9%). Furthermore, in both countries, irrespective of D/CI status, younger students were significantly more likely to be victimised and there were no significant gender differences. Moreover, children with D/CI were significantly more likely to be victimised in both Ireland and France. Irrespective of country and D/CI status, being a victim of bullying was related to low levels of classmate support and difficulty with communicating with fathers, and this was stronger for children that reported D/CI.

Conclusion

Like research undertaken in Northern Ireland on school bullying, much of the research carried out in the Republic of Ireland has been sporadic in nature, focusing on the incidence, nature, and correlates of bully/victim problems. Similar methodological shortcomings were also apparent (i.e., definitions, measures employed, time-reference period and reporting of findings).

CONCLUSION

The aim of the present chapter was to build on the foundational work of Mc Guckin and Lewis (2003) on Northern Ireland and Byrne (1999) on the Republic of Ireland by providing a contemporary review of school based bully/victim problems in both Northern Ireland and the Republic of Ireland. Data were presented from a total of 15 studies located in Northern Ireland

and 13 studies located in the Republic of Ireland. The findings suggest that, across a range of samples and measures, traditional bully/victim problems among school children continues to remain a problem in schools across both Northern Ireland and the Republic of Ireland. The findings also suggest that cyberbullying is an emerging and important area of further attention (see Mc Guckin, in press; Mc Guckin, O'Moore, & Crowley, 2011), as is research on disablist bullying (see Northern Ireland Anti-Bullying Forum, 2010; Purdy, & Mc Guckin, 2011; Sentenac et al., 2011).

The value of the present review is that it brings together data reported on school bullying in both Northern Ireland and the Republic of Ireland from a variety of different sources, including reports, as well as peer reviewed articles, therefore making the work more accessible to future researchers. As evidenced in this review, research since the pioneering studies of Callaghan and Joseph's (1995) work in Northern Ireland and Byrne's (1987) work in the Republic of Ireland research has continued to grow in terms of theoretical and methodological sophistication. Future work is now required to build on this growing body of research, with specific focus on the employment and evaluation of validated interventions (e.g., Jimerson, Swearer, & Espelage, 2010).

Chapter 63

YOUTH CYBER-BULLYING: RISKS, INTERVENTION AND PREVENTION

Tali Heiman* and Dorit Olenik Shemesh#

Department of Education and Psychology, The Open University of Israel, Raanana, Israel

ABSTRACT

Now days, there is no doubt that among adolescents and youth, the Internet communication is the most important use and the most popular for conversations, entrainment, personal refection, etc. The paper will examine the cyber-bullying (CB) phenomenon and its various effects in adolescent populations. It will illustrate the unique characteristics of CB in comparison with face-to-face (f-2-f) bullying, as well as describe the different roles in CB: victims, perpetrators, and witnesses (bystanders). We shall focused on revealing the risk factors associated with CB among adolescents and youth, point on the main intervention and prevention plans aimed at effectively coping with this phenomenon, mainly among adolescents, and future examination regarding college students technological misbehavior.

Keywords: Cyber-bullying; Risks, Intervention, Youth

INTRODUCTION

The use of social networks has expanded and become a prevalent phenomenon. Today, cyber-reality and social networks provide an opportunity for young people to familiarize themselves with new worlds, to learn and acquire knowledge and friends. Findings of a research study (O'Keeffe, and Clarke-Pearson, 2011), on youngsters' usage patterns of social networks and their consequences for children and adolescents, indicate that the use of social media is the

most common activity among children and adolescents, while the internet is becoming a daily tool for teenagers, cyber-bullying (CB) and cyber-insults are also becoming a frequent phenomenon among those youngsters. There is no doubt that adolescents' increasing use of computerized media has numerous advantages, such as speed and ease of information search and location, as well as exposure to a wide variety of content. The uncontrolled exposure to various types of content may constitute a risk factor for violence and a new type of aggression – cyberbullying. Thus the extensive use of the digital technology might pose risks of emotional and social harm and this new form of adolescents' violence and victimization may be related to negative psychosocial outcomes. For example, Beran and Li (2005) found a correlation between the incidence of different emotions and the behavior of the victims in connection with cyber aggression, as anger, sadness, anxiety, embarrassments, crying, fear, and self-blame; other studies (Dodden et al., 2009; Patchin and Hinjuda, 2006) pointed on feelings of sadness, depression and loneliness effects.

DEFINITIONS AND CHARACTERISTICS OF CYBER-BULLYING

Cyberbullying refers to a negative activity aimed at deliberate and repeated harm, while using a variety of electronic media, through which threatening and offensive messages are sent and received. This aggression use of the internet by a person or a group of people is mostly done anonymously in order to harm another person who cannot defend himself (Kowalski, Limber and Agatston, 2009; Smith et al. 2008). Cyberbullying can be viewed as a new form of school bullying that involves the use of electronic devices and/or other forms of information technology. In contrast to other forms of bullying, it reaches a far wider audience at rapid speed, transcending boundaries of time, and physical and personal space (CyberTraining, 2008).

It appears that CB has similar characteristics to face-to-face (f-2-f) bullying; in both phenomena, aggression is deliberate and it usually occurs more than once. Nevertheless, CB has a number of unique characteristics distinguishing it from f-2-f bullying:

A. *Anonymity* – While in f-2-f bullying the bully and the victim see and identify each other, in most CB cases, the participants on the net remain anonymous; they can share with others or reveal personal details of another person without exposing themselves (Heirman and Walrave, 2008). Moreover, cyberbullies do not personally confront their victims or acknowledge the consequences of their actions (Dehue, Blman, and Vollink, 2008).

B. *A wide audience* – While f-2-f bullying is limited to the number of people who can be harmed directly, the internet enables a large number of people to be reached faster, thus increasing the risk of CB (Heirman and Walrave, 2008).

C. *High accessibility* – the internet is accessible everywhere and anytime, therefore users can conduct aggressive behavior any time (Shariff and Hoff, 2007), unlike in f-2-f bullying where physical contact is required between the perpetrator and the victim.

D. *Difficulty in detecting and reporting* – In many cases of f-2-f bullying, signs of violence can be seen on the victim, whereas detection of CB victims is more complicated. Cyber-victims are less likely to report bullying than victims of f-2-f bullying, and since the harm is emotional rather than physical, it is harder to detect and treat (Heirman and Walrave, 2008).

E. *The means of aggression* – The means used by cyber-bullies are computers and/or cellular phones, using diverse technological methods, as sending harassing and humiliating text

messages, video clips and photos. Cyber-bullies may transfer personal details of a person to others, impersonate someone else, impose bans, blackmail, make inappropriate use of the virtual space, post denigrating contents, etc (Barak, 2006; Mason, 2008).

Willard (2005) addresses seven forms of CB: 1) Flaming: Online messages accompanied by angry and vulgar language; 2) Harassment: Repeatedly sending offensive, rude, and insulting messages; 3) Stalking: Repeated threatening and humiliating messages, inciting fear and insecurity; 4) Denigration: denigrating, sending or posting cruel gossip or rumors about a person to cause damage or embarrassment to a certain person; 5) Impersonation: Pretending to be someone else and sending or posting material online that gets that person in trouble, or damages that person's reputation or friendships; 6) Trickery: Sharing someone's personal details and secrets online; tricking someone into revealing secrets or embarrassing information which is then shared online; 7) Exclusion: Intentionally excluding someone from an on-line group, preventing a group of friends from contacting a person, or "blacklisting" a person.

PREVALENCE OF CB

Studies conducted regarding CB indicate that this phenomenon has constantly been on the rise in the last decade especially in Europe, the US and Australia, mainly among children and adolescents. For example, findings of EU KidsOnline projects which examined the CB (<http://www2.lse.ac.uk/media@lse/research/EUKidsOnline/ParticipatingCountries/Home.asp>) in 23 European countries indicated that around 25% of school pupils are directly involved in cyberbullying. A study conducted in the southern United States indicated that among a random sample of 4,441 youth (aged between 10 and 18) from 37 different schools during 2010, approximately 20% of the students report experiencing cyber-bullying in their lifetimes (Cyberbullying Research Center, 2010). An Australian survey, examining cyberbullying experiences among adolescents and young people (aged from 13 - 25) revealed that around half (49-52%) of the sample experienced cyberbullying between the ages of 10 and 14. It appears that in most cases, participants experience CB by emails, online chatrooms, social networking sites and mobile phones (Price and Dalgleish, 2010). The differences in prevalence reports can be caused by a wide range of definitions and the researchers' practical interpretation of the term 'harassment' or 'CB' compared to the adolescents' interpretation of this phenomenon.

A comprehensive study conducted in the US. found that one in five young online users was involved in CB in some way (Ybarra and Mitchell, 2004), and over 53% reported they knew someone who had been victimized on the internet (Li, 2006), while most of the children who fell victim to CB were also victims of f-2-f bullying (Shariff and Hoff, 2007). Other studies revealed 20-35% prevalence among school-age children (Hinduja and Patchin, 2008). Findings of other studies in Europe indicated that about 20% of teenagers aged 7 -20 who used the internet reported repeated experiences of CB during the year (Vandebosch and Van Cleemput, 2008). Findings in studies conducted in Israel, indicating that 13% of adolescents reported that they had sent a hurtful message, 45% had received hurtful messages on IM, 16% in chat rooms, and 6% via emails (Lamish and Ribak, 2006; Weisblay, 2010). In an additional study of CB involvement, conducted among 558 Israeli adolescents (54% boys, 46% girls) aged 13-16, the finding revealed that 15.8% of the participants were victims of CB (Heiman and Olenik-Shemesh, 2011).

TYPES OF CB: PERPETRATORS, VICTIMS AND WITNESSES

The population actively or passively involved in CB includes three types of ‘participants’: the perpetrators or the bullies, the victims and the witnesses.

The Perpetrators

The perpetrator or cyber-bully is a person who deliberately sends verbal or visual messages (photos, video clips) in order to threaten, intimidate, hurt or humiliate another person. Several studies pointed to the characteristics of cyber-bullies, such as a low level of peer social support, their sense of detachment from school, and/or lower school achievements (Calvete, Orue, and Li, 2007; Villardo'n and Padilla, 2010; Williams and Guerra, 2007). Furthermore, it was found that cyber-bullies are also prone to negative behavior outside the internet, including physical aggression, vandalism, theft, and cigarette and alcohol consumption (Ybarra and Mitchell, 2004a).

In an attempt to explain the motives for CB perpetration, it has been suggested that the bully's actions as deriving from the wish for vengeance, a sense that ‘the victim deserves it’, to have fun (Hinduja and Patchin, 2009), or the need for instant gratification (Dooley, Pyzalski, and Cross, 2009). Most cyber-bullies claimed that there was no real harm in their actions and they did not consider their actions as a type of bullying.

The Victims

CB victims are children, adolescents or youth who receive hurtful, offensive or threatening messages via the internet. They may also receive photos or revealing video clips, have their social network account broken into, or fall victim to various activities such as impersonation, spreading of rumors about them, etc. (Druck and Kaplowitz, 2005).

Studies examining the characteristics of CB victims pointed to a number of factors that can predict who may be victimized in or outside the virtual world, such as those with a low social status within their age group, low level of social integration, low self-esteem, behavioral problems at school, and a problematic relationship with their parents (Katzner, Fetchenhauer and Belschak, 2009).

Other studies (Arseneault, Bowes, and Shakoor, 2010) have addressed both the personal traits as well as environmental factors that may affect the tendency for f-2-f bullying. The similarity between CB and f-2-f bullying victims raises the possibility that some of the personal and environmental factors that cause adolescents to become victims outside the internet may account for the tendency to fall victim to CB.

The Witnesses

The witnesses are children and youth online who can see the hurtful messages sent to others, and occasionally they take an active part in CB, such as forwarding the messages to

others, or responding ‘behind the scenes’. Usually, the witnesses are highly exposed to peer-pressure; they are considerably affected by the perpetrators, and want to be valued by them and to belong to the stronger group (Druck and Kaplowitz, 2005; Twemlow, Fonagy and Sacco, 2004).

Only few studies have examined the witness group. Coloroso (2003) describes the witnesses of CB as a supportive group that encourages and empowers CB. Their support for cyber-bullies may range from minimal support to active and intensive support. Levine and Crowther (2008) noted that when the witnesses of f-2-f bullying are perceived as strangers, the chances of getting help from them decrease as their number increases. When the witnesses are considered as friends, the bigger their group, the more they are willing to help and intervene. Upon reviewing the unique characteristics of online witnesses, Willard (2005) pointed to two main groups: 1. the active group - witnesses who try to protest or prevent CB and help the victims, and witnesses who encourage and support cyberbullies; 2. the passive group - those who don’t intervene or don’t try to help the victim. Willard emphasizes that witnesses should be empowered and encouraged to report CB, since and by so doing they can help the victims and fight against cyber-bullying.

RISK AND PROTECTIVE FACTORS FOR CYBERBULLYING

Focusing on the risk factors associated with CB among adolescents and youth, revealed that some of the online risk and protective factors were also found in studies of f-2-f bullying, however some are unique and specific only to CB.

Risk factors are characteristics of an individual or the environment that increase the likelihood that the individual will behave in a certain way (Orpinas and Horne, 2006). Orpinas and Horne (2006) suggested that the root of the bullying problem lies in understanding and revealing risk and protective factors. They noted that the risk factors themselves do not cause the individual’s behavior, but the accumulated impact of a number of risk factors is a stronger predictor than the presence of one diagnosed factor. A combination of several risk factors associated with aggression or victimization increases the likelihood that an individual will adopt aggressive behavior, or that he will be victimized. On the other hand, protective factors are characteristics of an individual or the environment that help to decrease the chances of an individual behaving harmfully, or becoming a victim (Orpinas and Horne, 2006). Risk and protective factors are frequently two sides of the same coin, or represent the ends of the same continuum. It is noteworthy that, usually, when the specific factors are at the positive end of the continuum, they are perceived as protective factors, and inversely, the presence of a certain factor may prevent the risk factor to be manifested. For example, lack of social support may constitute a risk factor for CB and cyber-victimization while a high level of social support will be used as a protective factor for CB and violence.

The risk and protective factors for CB (see Figure 1) are based on an ecological model that examines different components regarding involvement in bullying: 1. individual, 2. family, 3. peer group, 4. school and, 5. community, culture and media (Orpinas and Horne, 2006).

1. The Individual Level

The individual level is composed of various personal aspects, such as the background of the person, and to personal, social and emotional characteristics.

a) Background factors mainly referred to age and gender. *Age*: Recent studies reveal that the average age for the onset of CB and victimization is around 10-12 and the peak of this phenomenon is around ages 13-15 (Beale and Hall, 2007; Druck and Kaplowitz, 2005; Hinduja and Patchin, 2009; Smith et al. 2008). The highest prevalence was found at ages 13-14 and at 16-17, when the prevalence begins to decrease (Williams and Guerra, 2007).

It was found that at age 10-11, the prevalence was the lowest (4.5%), whereas the highest prevalence was at age 13-14 (12.9%) while among high-school students (age 16-17) the prevalence of CB declined to 9.9% (Didden et al., 2009; Smith et al., 2008; Williams and Guerra, 2007). At age 12-19, adolescents are at the highest risk of being involved in CB (Straksrud and Livingstone, 2009), and from the age of 19, there is a decline in the reports of CB (Sevcikova and Smahel, 2009). However with the enormous facilities of computerized technology, it appears that nowadays, the age of involvement in CB for all types of participants—victim, perpetrator, and witness - is decreasing.

Figure 1. Risk and protective factors for cyberbullying – an ecological model.

Gender: Various studies showed that generally across cultures, boys behave more aggressively than girls; boys display more direct physical and verbal aggression, whereas girls display more indirect aggression and hurt others by damaging inter-personal relationships (spreading rumors, social ban, etc.) (Orpinas and Horne, 2006).

As to the question of whether gender is a risk factor for CB, as it is for f-2-f bullying, the answer is not unequivocal. For example, within Tokunaga (2010) review it was found that while boys are more involved in f-2-f bullying, girls are actually more involved in CB and the extent of their involvement is similar to that of boys (Hinduja and Patchin, 2008). A possible explanation is that CB (harassment, bans, psychological abuse) is a type of indirect bullying in which girls tend to be more involved. Other studies reported that girls are more likely to be CB

victims, whereas boys have an increased tendency to be cyber-bullies (Li, 2006; Smith et al. 2008), whereas other studies (Hinduja and Patchin, 2008) show no significant difference between boys and girls in the roles of victim and bully. A recent study shows a higher percentage of girls as cyber-victims, and a higher percentage of boys as cyber-bullies (Heiman, Olenik-Shemesh, and Eden, 2011). Further study is needed in order to examine whether gender is indeed a risk factor for CB.

b) Personal, social and emotional characteristics: Examining the correlations between cyber bullying and social-emotional aspects, it appears that internal personal characteristics such as anxiety, depression, solitude, psychosomatic complaints and low self-esteem (Goldbaum et al., 2000) are viewed as risk factors related to victimization, while almost similar measures, such as depression, a deep sense of solitude, social anxiety, low self-esteem, and difficulty in being assertive were found to be risk factors for CB perpetration (Didden et al. 2009; Ybarra, 2004). A positive correlation was also found between depression, suicidal thoughts and falling victim to CB by children in the same age group (Wang, Iannotti, and Nansel, 2009), particularly among boys (Ybarra, 2004). In a study conducted among more than a 1,000 adolescents, the risk of adolescents becoming cyber-victims was predicted by loneliness, lack of emotional competence and lower social support (Heiman, Olenik-Shemesh, and Eden, 2011).

In general, various types of social difficulties, depression, and a sense of loneliness constitute risk factors that may increase the chance of experiencing cyber-risks (Ybarra, Mitchell, Finkelhor, and Wolak, 2007). There are students who seek to compensate for their lack of social contacts by finding refuge on the internet, where they do manage to develop relationships even if they are of a negative character (Peter, Valkenburg, and Schouten, 2006). Adolescents with low self-esteem and a poor relationship with their parents, also encounter more cyber-risks (Livingstone and Helsper, 2007).

Although there is a positive correlation between the intensity of the sense of loneliness and depression and the extent of internet use (Mason, 2008; Patchin and Hinduja, 2006), the social isolation and sense of depression may be the reasons for increased internet use. It is possible that it is particularly the sense of depression and solitude that leads teenagers to look for anonymous relationships on the internet. On the other hand, depressed and socially isolated teenagers are more likely to be cyber-victims. Although it seems that children who suffer from CB experience increased depression and solitude and suffer from low self-esteem (Van den, Vermulst, Van Rooy, and Meerkerk, 2006).

Traits that were found to increase the risk of becoming a cyber-bully such as impulsiveness, aggression (Ybarra, Mitchell, Finkelhor, and Walak, 2007), dominance, ease of frustration, difficulty in adhering to rules, susceptibility to changing moods and manipulation (Kowalski, Limber, and Agatston, 2000). In addition, a low level of empathy is a risk factor for involvement in CB and in traditional bullies (Ang and Goh, 2010). It appears that general and social/emotional loneliness is a risk factor for victims as well as cyber-bullies. Behavioral problems outside the internet such as alcohol consumption and absence from school may also be a risk factor for involvement in CB (Hinduja and Patchin, 2007).

Furthermore, there is a group of adolescents who are victims and bullies at the same time. Thus, children who are victims for prolonged periods may adopt bullying and aggressive strategies as a defense means against those with more power, and may even become bullies themselves as way to deal with their frustrations and anger as a result of their victimization (Goldbaum, et al., 2003).

Involvement in f-2-f bullying: One of the most significant risk factors for involvement in CB is involvement in f-2-f bullying. A positive correlation was found between victimization on the internet and outside it (Li, 2007). Similar results were found in a study that examined CB among adolescents, where almost two thirds of victims who reported CB were also victims in the real world. In other words, the adolescent cyber-bullies were also involved in traditional bullying (Heiman, Olenik-Shemesh, and Eden, 2011). In a study that compared online risk factors with offline ones, it was found that students who are cyber-victims are considerably more likely to be victims of f-2-f bullying (Cross et al. 2011). Cross also found that cyber-victimization is occasionally related to school bullying, and students who are bullies online are also involved in offline bullying towards others, and they are more likely to be victims of CB.

The extent of exposure on the internet: It appears that students who tend to heavily use digital means, and have considerable experience in browsing the internet, experience a wider range of cyber-risks; the more frequent the use of the internet, chat rooms and blogs, the greater the risk of becoming a victim as well as a cyber-bully (Cross et al., 2011; Livingstone and Helsper, 2009).

Another study on this topic found that children who used the computer for less than an hour a day have a smaller chance of becoming cyber-victims than those who use the computer and internet for more than an hour a day (Didden et al. 2009).

Participation in social networks increases the risk of becoming cyber-victims, thus the mere involvement in a certain type of internet activity increases the risk of falling victim to CB (Mesch, 2009). Mesch pointed out that adolescents have confidence and trust in others, they tend to expose many of their personal details, which increases the risk of becoming a cyber-victim. Making contact with strangers online also constitutes a risk factor for becoming a victim. The fact that social networks require the creation of a personal profile and providing information to others regarding personal traits and ways to make contact exposes the adolescents to various forms of CB.

Nevertheless, some claim that sometimes children with lower online experience are at a higher risk of being hurt by people they meet on the internet whom they then meet later in reality (Staksrud and Livingstone, 2009). Therefore, access and exposure to online areas is a risk factor for cyber-victims. This exposure includes owning an active profile in a social networking site, participation in chat rooms and online games, high frequency of correspondence with network friends (such as Facebook), considerable use of IM, SMS and emails, and willingness to share personal information on the internet. Mesch believes that the risk of victimization increases when there is a combination of area, appropriate targets, motivated bullies and lack of supervision (Mesch, 2009).

2. The Family Aspect

The family is a central source of teaching and support from the child's birth, and has a strong influence on the development of risk and protective aspects of the child's behavior. During the child's development, friends and peer age groups also play that important role in the child's life. Poor communication and weak relationships between parents and their children and lack of parental supervision are risk factors for involvement in bullying (Cohen et al., 2002; Duncar et al., 1995).

Consistent findings on bullying shows that parents of bullies lack parental warmth, support and authority, supervision and clear boundaries, and sometimes the bullies suffer from parental rejection and the parents themselves may be a model for aggression (Baldry and Farrington, 1998).

For example, it was found that schoolchildren who were victims of CB noted two main reasons for the lack of parental involvement in their experiences as CB victims: 1) victims fears that if they inform their parents about CB, the parents will prohibit their use of the internet; 2) the children have the impression that adults (their parents, teachers) are not familiar with computerized technology, and are unaware of the virtual life adolescents lead via the internet (Campbell, 2007).

Family risk factors indirectly increase the likelihood of bullying, and affect the child's choice of friends, who may influence him/her to be involved in bullying. Therefore, in daily life as in cyberspace, one of the risk factors for bullying behavior is a problematic relationship and weak connections between adolescent and parents (Ybarra and Mitchell, 2004).

3. Peer Group Aspects

Peer groups and close friendships are very valuable to adolescents and have frequently been studied in the context of violence. The peer group serves numerous and important functions in the lives of adolescents and in their coping with tensions, social comparison, peer pressure to undergo experiences, social status, handling power and authority (Smilansky, 1985). The importance of the peer group rises considerably, and friendships develop very intensively. The peer group at this age is a very significant reference group for adolescents (Espelage, Holt, and Henkel, 2003).

The peer group can also function as a risk as well as a protective factor for involvement in CB. Cyber-victims usually have the smallest network of friends (Salmivalli, Huttunen, and Lagerspetz, 1997).

It seems that, apart from popularity and the number of friends, which were found to be related to the status of victim, the quality of friendships also has a role in defining the victim (Hodges et al. 1997). Poor social skills and low social support were found to be risk factors for cyber-victimization. Adolescents whose quality of friendships is insufficient do not enjoy the support of their friends, and also suffer from a lack of friendship qualities, such as trust and affection, that may support them in coping with victimization.

On the other hand, as mentioned before, bullies are located at two ends of the social popularity continuum – there are bullies with high social status and popularity, and bullies with low social status and no popularity.

4. The School Level

School systems are included in the child and adolescent's close surroundings, and there are factors related to school – from academic achievements to school climate – which constitute risk factors for bullying. Repeated failures at school, low grades, lack of involvement in class, poor learning skills, low expectation of success, an ineffective disciplinary system – all those were found to be unique risk factors for bullying on the school level (Orpinas and Horne, 2006).

Pupils who drop out of school are at high risk of deteriorating into aggressive and bullying behavior, and aggressive children usually experience deterioration in their relations with their teachers and other classmates. Findings are inconsistent when examining the relationship between cyber-victimization and school grades: results shows that students with high academic achievements were usually a target for bullying and are at risk of cyber-victimization (Li, 2007; Ma, 2001).

So it is possible that particularly students with high academic achievements are targets for CB. On the other hand, it was also found that Cyber-victims have lower school grades (Cross et al. 2011).

5. Community, Culture and Media Aspects

Bandura (1986) stated that life in an unsafe and aggressive community provides opportunities for children to learn aggressive behavior. There is a significant exposure to media and to various digital means that considerably influence behavior, which increases the risk of aggressive behavior among spectators, and repeated exposure to aggressive behavior in the media, may change the individual's attitude toward violence, and teach aggressive behavior (Anderson et al. 2003).

The considerable use of the internet around the world and easy access and exposure to digital media constitute risk factors for involvement in CB in the following roles: bully, victim and witness. On the community level, public awareness of this issue, and the development and establishment of a policy with clear rules may serve as protective factors (Staksrud and Livingstone, 2009).

PROTECTIVE FACTORS

The risk factors mentioned above can also serve as protective factors. For example, close and caring relationships with parents, were found to be protective factors against CB perpetration and even victimization. Good communication with their parents' helps children feel safe enough to approach their parents and consult with them when a problem or disturbing issue arises. Studies from the past 15 years showed that parents, mainly those who maintain positive relations with their adolescent children, are still the main source of influence for adolescents (Steinberg and Moris, 2001). In addition, the peer group is perceived as a central factor in the life of the adolescent, it is particularly in adolescence that parents and family have a unique importance, and they can be a source of support and advice in the adolescents' confused world.

In summary, the online environment has created new risk factors that are not experienced in offline encounters. Risk and protective factors have a central role in establishing prevention and intervention programs. Prevention and intervention programs require risk assessment and discovery of protective factors that can be used to reduce the risk of victimization, and to promote adjustment and protection capabilities.

INTERVENTION AND PREVENTION FOR CB

In Western society there has been an increase in children's and adolescents' use of the internet and in concerns over the risks posed in their exposure to online content, and their vulnerability. The attempts to develop intervention and prevention plans against CB have created a variety of dilemmas in many countries. On the one hand, the technological, educational and social world supports internet use, and the development of curiosity and creativity, exposure to information and opportunities for personal development. On the other hand however, due to concern over risks posed on the internet and the desire to reduce them, there is an attempt to limit children's access to the internet (Staksrud and Livingstone, 2009). Solutions to this dilemma, whether by ignoring the risks or limiting internet access, have been insufficient, and it appears that more appropriate intervention and prevention solutions are required, while addressing risk management in a more efficient and calculated manner.

Examining the coping strategies of cyber-victims (Hinduja and Patchin, 2009), it seems that in the absence of adult assistance, the child /adolescent cyber-victims will try to solve the problems on their own. Among the common possibilities, it was reported that some of the victims blocked the names of the cyber-bullies or their email addresses (25% of the victims); other victims took a break from the computer or the internet as a solution (23% of the victims); some reported they changed their user names or their email account (10%), and a few victims said that they turned to the police because they felt a real threat to their lives (2.7%).

Based on the findings that two thirds of parents claimed their children know how to cope with such cases (Staksrud and Livingstone, 2009), studies in several European countries (Belgium, Denmark, Estonia, Holland and Sweden), examined the correlation between the parents' perceptions of the likelihood that their children will be exposed to hurtful content on the internet, and their perceptions of their children's coping ability. Results revealed that parents who tend to attribute little importance to the risks do not express concern over the child's coping strategies with this content. On the other hand, when parents do attribute considerable importance to the risk, they express concern regarding their children's ability to cope. The results of the parents' report in Cyprus and Austria, strongly indicated that the more the children encounter online risks, the more their parents estimate that their children know how to cope, whereas children who encounter fewer online risks do not know how to cope with them effectively. The researchers estimate that the difference between the countries derives from low awareness of cyber-risks (Cyprus, Austria), compared to countries where the internet is used more (Staksrud and Livingstone, 2009).

Prevention and intervention plans as displayed in programs developed in countries such as Australia, the US., Canada and Western Europe, address various aspects of children's and adolescents' life circles. These circles refer first to social relationships at school and in the family framework. For each of these systems, several intervention plans and techniques were developed in order to reduce aggressive behavior, and offer coping strategies that can prevent victimization. Effective intervention should include components addressing the risk and protective factors, awareness development, helping the victims make contacts, how to win peer support and protection, building trust, and promoting social skills that may prevent future CB perpetration and victimization (Goldbaum, Craig, Pepler and Connolly, 2003).

Various plans aimed at preventing and coping with school bullying. The creation of a positive, caring and supportive atmosphere at school may serve as a protective factor and reduce

the extent of bullying (Orpinas and Horne, 2006). In adolescence, critical importance is attributed to the level of social status and popularity, but at the same time, adolescents' sensitivity level is particularly vulnerable and may change according to their social positioning, whether in an f-2-f or online environment; therefore, in order to be cautious and protect the children, researchers recommend placing the computer through which the internet is accessed in the most central location at home (Mesch, 2009; Orpinas and Horne, 2006), and holding conversations between parents and children/adolescents about online risks.

Willard (2005) presents a comprehensive program which includes the child's educational, psychological and social frameworks. For example, in the educational framework, activity is carried out which is designed to detect and identify CB among students, and which develops a policy towards CB, and guides and instructs teachers how to teach students about the dangers in cyberspace. This is done through guidance booklets, video films, questionnaires and class discussions. Additional activity is focused on the school's psychological staff. The staff is guided on how to assess the extent of an individual's vulnerability, what to advise to the teachers, the students and their parents, and how to implement it. In the framework of the psychological staff's assessments, they are entrusted with anger management plans, development of social skills and inter-personal communication, providing tools for the solution of social problems and assisting the parents. In the social context, the program recommends extra-curricular activity that promotes social 'codes', community programs, a unified behavioral policy, while support and assistance as well as disciplinary and punitive rules are offered. Similarly, others researchers (Staksrud and Livingstone, 2009) point to programs adjusted to various populations such as students, teachers and parents. For example, students may be recommended to undergo self-regulation training, while teachers and parents will practice raising awareness of the phenomenon, with support and guidance to cope with the children's reactions.

CONCLUSION

There is no doubt about the internet's positive contribution for adolescents. It is a source of personal growth, information acquisition, an opportunity for new acquaintances, empowerment, emotional expression, boosting of self-confidence and openness, and paves the way for social dialogue and relationships outside the internet (Ybarra and Mitchell, 2004b). Nevertheless, according to various studies (Mason, 2008), as internet use increases, so do the dangers of exposure to CB, and personal exposure, such as through blog writing (Huffaker, 2006).

Various studies indicate that CB is almost certain to have painful consequences' and can also affect many areas of adolescent life. Similar to f-2-f bullying, which affects the victim's capabilities and achievements, so CB can cause a decline in the ability to function at school, a decrease in the concentration level, in the motivation to study and also cause absences from school (Shariff and Hoff, 2007; Ybarra, Diener-West and Leaf, 2007). Moreover, cyberbullies may have a negative social and emotional effect (Ybarra and Mitchell, 2004; Patchin and Hinduja, 2006), cyber-victims may change their behavior, and become reclusive, or react aggressively. The victim typically feels psychological distress, low self-esteem and social difficulties (Kowalski and Limber, 2007; Mason, 2008), while a sense of isolation and

depression may cause both aggressors and cyber-victims to become involved in violence and crime, and there have been extreme cases where CB has led to suicide (Patchin and Hinduja, Ybarra and Mitchell, 2004). Furthermore, researchers point to the risks of social/mental damage to adolescents who are active online due to a rise in their anxiety and depression level, a sense of distress or failure, social rejection, social bullying and exposure to sexual content (O'Keeffe, and Clarke-Pearson, 2011).

While social life in the educational framework used to take place during the day time, nowadays internet usage continues through afternoon hours into the night. The internet has become the "social reality", a kind of alternative to the playground of the 1960's and 1970's, or an alternative to the endless phone calls in the 1980's and 1990's. Therefore, since it is hard to distinguish between real and virtual life, abusive online activity may have painful consequences for the individual.

There is no doubt that intervention and prevention programs need to be developed and installed in the educational as well as family frameworks. Programs are required to be installed as part of the school curriculum, raising awareness of f-2-f bullying and CB, as well as teaching and guiding the students to acquire social skills and to cope effectively with the risks. In addition to guiding and working with the student, the educational team needs to be instructed on how to assist at-risk students, and to aim at balanced activity on the social networks. Therefore, considerable importance is attached to the development of effective strategies to deal with cyberbullying situations that will constitute protective factors against the possible frustrating circumstances.

Chapter 64

CYBER-BULLYING: EMERGENCE, CURRENT STATUS AND FUTURE TRENDS

Dr. Ria Hanewald*

Deakin University

ABSTRACT

Cyber bullying is a very recent phenomenon, in existence for only a decade and a half. However, since its first appearance in the late 1990's it has gone through four distinct stages, each characterised by the available technology, namely hardware and software. Parallel to these advancements in cheaper, easier and more widespread access time online increased and with it the risk of inappropriate and unsafe interactions. In an effort to combat cyber bullying, cyber suicide and more recently sexting, a plethora of intervention and prevention programs have been designed and implemented by governments, educational authorities and child protection agencies. In addition, expensive Internet software filters and blocks have been developed and implemented to shield children and young people while at school from inappropriate content and contact. Despite substantial funding and a patchwork of initiatives, cyber bullying has steadily increased. Some endeavours are emerging to evaluate and subsequently improve the effectiveness of these efforts. Alongside these educational attempts, new legislation to persecute cyber bullying has been introduced and a number of convictions have been issued.

This chapter will trace the emergence and infancy of the field of cyber bullying, identify the main issues and outline the current state of the research evidence. It is hoped that it will illuminate readers who are new to the problem of cyber bullying with solid background knowledge. For others, who are accustomed with the literature on cyber bullying, it is aimed to refresh their memories and extend as well as up-date their knowledge.

INTRODUCTION

The phenomenon of cyber bullying and its field of enquiry have existed for merely 15 years. During that time, it has gone through rapid and diverse development starting with its emergence in the late 1990's. Its first phase of empirical research in the early 2000's in predominately English speaking countries of the developed world focused on establishing the nature and extent of the behaviour. The second phase in the mid 2000's is characterised by studies on the various environments in which cyber bullying takes place, on typifying the young people that are affected and the impact it has on their health and wellbeing. It is especially pertinent with the advent of cyber suicides where children take their own lives because they have been cyber bullied. This period also sees the proliferation of a plethora of intervention and prevention programs funded by governments, educational authorities and child protected agencies to prevent cyber bullying and to educate young people on safe online behaviour. The third phase in the late 2000's sees the continued growth of cyber bullying especially in social networking sites, the emergence of empirical research from non-English speaking countries of the developed world, the first attempts to evaluate the patchwork of educational initiatives with their often contradictory messages, and the introduction of legislation to persecute cyber bullying. The beginning of the 2010's heralds the availability of cheap mobile devices (for example smart phones, tablets like the iPad or Android) and wireless access which gave rise to sexting, which is the sending or receiving of sexually explicit messages or images via handheld appliances. Sexting can be either due to cyber bullying or because of digital risk taking by a young person. Regardless of intent both behaviours can result in convictions for child pornography or exploitation depending upon the legislation in the respective country. A criminal record for those involved will have with detrimental consequences for their future education and employment prospects.

Despite the evolution of a research community and a number of notable authors publishing on cyber bullying, there is still no commonly agreed definition on cyber bullying and its characteristics. The range of varying classifications and behaviours still plagues the field, hinders cross-study comparisons, prevents the design of a universally accepted measurement tool, and thus the systematic, reliable and replicable evaluation of the cornucopia of prevention and intervention program.

It is anticipated that the increasing trend in cyber bullying, cyber suicide and sexting with permeation into virtual worlds will create greater demand for intervention and prevention programs. Currently, lacking evidence of their impact and limited funds for future initiatives will necessitate empirical research to evaluate and establish their effectiveness. The severe outcomes of cyber bullying behaviours will also see increased introduction of related legislations and legal cases in which educational institutions, teachers and parents will have to prove that they complied with their duty of care. In turn, this will trigger the implementation of additional protection strategies such as school guidelines and acceptable use policies, the installation of internet filter and blocks to school networks or computers, mandatory professional development on digital safety for educators and introduction of digital citizenship classes into the curriculum.

This chapter outlines the emergence, current status and future trends in cyber bullying to give the novice reader an introduction to the issues and provide a background context for the

following chapters in this book. It also provides a succinct overview for those readers who are familiar with the development of cyber bullying and its associated research literature.

THE EMERGENCE, CURRENT STATUS AND FUTURE TRENDS

Cyber bullying emerged about 15 years ago, has increased and changed alongside the invention of new technological devices combined with cheap and fast Internet access. It will be argued that these changes occurred in three to five yearly increments, parallel to innovations in technology. These time frames designate the stages with the field of cyber bullying, which is now moving into its fourth stage. The individual stages will be captured and explained in an attempt to provide a chronological and thus easy to understand account. It has to be acknowledged that such a report in the space of a book chapter will deal with the major issues only and is thus only summative rather than explicitly detailed in nature.

Stage 1: The Emergence of the Internet and with it Cyber Bullying (Late 1990's)

The release of the World Wide Web in 1992, Mosaic in 1993 and Netscape Navigator in 1994 caused the shift from stand-alone microcomputers to networked personal computers. This brought global connectedness to a growing number of people who used improved hardware and software to access the Internet relatively easy, cheap and fast. It allowed unlimited access to information for entertainment but also for education, offering rich learning opportunities for children. Alongside these benefits, it also brought dangers for these young people such as exposure to inappropriate content (for example sexual, racist violent) or unwanted contact with other Internet users.

One of these online risks is cyber bullying (also spelled cyber-bullying), which is now the most commonly used term by scholars (Herring, 2002; Willard, 2003; Kowalski, Limber & Agatston, 2005) in the English speaking world. European continental countries were yet to engage in the issue and later adopted the term of cyber mobbing, derived from traditional, face-to-face mobbing behaviour. Initially, a range of terms were in circulation such as online bullying, online harassment, online harm, internet bullying, electronic bullying, electronic harassment, cyber abuse, cyber misuse, cyber harassment or cyber stalking. They were used interchangeably and without clear definition or categorisation of associated behaviours, a deficiency that has persisted and hampered efforts in the field.

Bill Belsey, a Canadian Educational Advisor has been credited with coining the term of cyber bullying, which he defined as "...the use of information and communication technologies to support deliberate, repeated, and hostile behavior by an individual or group, that is intended to harm others" (Belsey, n.d.). At the core of this definition is the intent to harm and the repetition of the behaviour. These notions have since been challenged by other scholars (Shariff, in press) who argue that cyber bullying can be a one-off incident and the intention can be one of jesting, although the joke may not be perceived as such.

The first attempt to classify the range of harmful activities conducted through mobile and networked technologies was made by Susan Herring (2002) who had identified four different

forms of cyber violence, namely cyber stalking, degradation, harassment and a category entitled online contact/ off line harm. Much like stalking in the physical world, cyber stalking involves the monitoring of a person's online activities combined with unwanted contact. This invasion of privacy is intimidating and causes fear in the victim but fulfils the stalker's desire for control and power, which is accentuated when the stalking behaviour moves from the virtual world to the real life world. Online harassment includes words or actions that alarm, abuse or bother others (for example name calling, rumours, mocking) whereas degradation is used to describe sexual, racial, religious or political insults against individuals or whole groups. Criminal intent is behind online contact that leads to off line harm as the target is 'groomed' through the virtual contact in order to gain their trust. Once this has been achieved, the perpetrator arranges to meet them in real life to take advantage of them either sexually or financially.

Nancy Willard (2004) expanded these four categories to seven but also modified the initial terms and their associated behavior. Online harassment was now the repeated sending of offensive messages to a person, whereas cyber stalking was the intimidating of a person through threats and degradation became denigration, defined as circulating false or cruel information about a person. Added was exclusion (leave somebody intentionally out), flaming (sending rude or angry message about someone), masquerading (posing to be another person and posting material in their name) and outing (circulating private exchanges or images to embarrass or humiliate).

Adding to this growing range of labels and behaviors were Kowalski, Limber and Agatston (2005) who used the umbrella term of cyber bullying to group cyber harassment, cyber stalking, denigration, exclusion (or ostracism), impersonation, outing & trickery together.

Yet again, a number of different descriptors for various behaviours under the umbrella term of cyber bullying were offered by Hanewald (2010) and are displayed in tabular form below.

Table 1. Cyber bullying terminology and their definitions

Terminology	Definition
cyber abuse	defamation of character, coarse language, name calling, personal attacks
cyber harassment	offensive messages to annoy, alarm or abuse others
cyber stalking	unwanted contact to invade a person's privacy and exert control over them
denigration	spreading of false or deprecating information through text or images
degrading	sending racial, religious, sexual and political insults through text or images
exclusion	deliberate refusal to accept others, particular in social networking sites
flaming	short, heated exchange between two or more people
impersonation	posing online as another person to send malicious information in their name
trickery	betrayal through sharing of private exchanges or images to humiliate the target

As indicated, these differences in the use of terminology and definitions have endured, hampered progress in the field and highlight the need for a universal taxonomy. This lack of agreement will plague the measurement of cyber bullying prevalence, comparison of cross-study results, and the development of prevention and intervention programs and their effectiveness measures, which will be discussed later in more detail.

Cyber bullying (much like its European counterpart of cyber mobbing) seems to have won dominance as the preferred term in the literature due to its derivation from conventional bullying in the physical world.

Traditional, face-to-face bullying in real life contexts offers already existing explanations for the motivation and behaviour dynamics of the perpetrator, the victim and any potential bystander(s). The parallels between traditional and cyber bullying in terms of motivation and behavior pattern were noticed by Shariff (2004) who surmised that the impact would also be similar.

These similarities have led scholars to assume that cyber bullying is the same as traditional bullying except that it happens online (Li, 2004). This view assumes a shift from one environment into another. Following that line of argument, physical bullying would be replaced by cyber bullying. It seems at first glance a much safer alternative due to the absence of physical contact which might involve punching, kicking, hitting, pushing or spitting. Bullying in front of a computer screen is limited to psychological and emotional aspects. However, the damage caused might be more severe as the incidents of cyber suicide (discussed in stage 4) will reveal.

The view that cyber bullying is an extension of the traditional bullying occurring in schools was put forward by Shariff (2005). It implies that bullying in the school yard is continued after school as students carry it over into the virtual world and keep the inappropriate behaviour going as cyber bullying, which would make it an addition rather than a substitute. Ybarra and Mitchell (2004) also suggest a connection between face-to-face and cyber bullying but as a role reversal. They found in their research that more than half (51%) of young people who are victims in face-to-face environments are much more likely to bully online. The victim of real-life bullying turns into the online perpetrator. This flip flop of roles is motivated by revenge. Doing so while hiding behind a computer screen and being anonymous is less dangerous for the victim than openly confronting a tormentor in a face-to-face situation. While cyber bullying their face-to-face bully may protect from discovery and punishment it carries the risk that their identity is found out, which might further agitate the situation. Taking this logic a step further, for the victim of face-to-face bullying, cyber bullying a stranger is even safer as the risk of detection is much smaller but the need to feel power and vindication is still satisfied. By acting out and tormenting an innocent third party, the cruelty is perpetuated. To summarise this point, while there seems to be a link between face-to-face bullying and cyber bullying, the exact nature of it is unclear but it most likely retaliation combined with the desire for power and control.

As already indicated face-to-face bullying between peers is not new. Jenkins and boyd¹ (2006) assert that bullying, harassment and sexual teasing is epidemic amongst young people because these are the very tools that enable them to make meaning of social status, roles, cultural norms and popularity.

There is usually a verbal component such as sarcasm, ridicule, teasing, name calling or deception and a physical aspect such as hitting, kicking or biting or a combination of both in traditional bullying. There is usually a perpetrator and a victim who gets picked on because they are considered to be different and strange as well as one or my bystanders (Campbell, 2005; Limber and Small, 2003).

Traditional bullying was not seen as a serious problem but merely a phase or developmental difficulty that young people went through in puberty and eventually grew out of as they matured. This rather slack attitude changed swiftly after 49 people were killed across 24

¹ danah boyd insists on the non-capitalisation of her name for personal and political reasons (boyd, 2009).

American schools. As this wave of shooting was investigated it was found that all killers had been bullied by their peers (BBC news, 2007). During their prolonged ordeal, they received no support or intervention from their school administrators. This inaction in the face of repeated bullying and the dire consequences triggered the introduction of anti-bullying programs and zero-tolerance policies in schools (Dedman, 2000).

It might have been this complete ban of face-to-face bullying in schools that pushed bullying into cyber space, especially since it coincided with the availability of cheap, fast and easy Internet access. Or it might be that cyber bullying is merely a modern day version of face-to-face bullying that has always happened before, during and after school. In any case, it is obvious that cyber bullying is becoming increasingly prevalent as young people increase their use of technology (Smith, Mahdavi, Carvalho & Tippet, 2006).

Stage 2: Investigations on the Nature and Extent of Cyber Bullying (Early 2000's)

After the emergence of the phenomenon in the late 1990's and some endeavours to identify, label and describe it in order to gain some understanding of it, the second stage in the development of the field was marked by endeavours to establish the prevalence of cyber bullying. The first empirical studies became available that were investigating the issue by identifying its nature, frequency and duration, places and the online environments in which it mostly occurred, behaviour patterns of cyber bullies, their profile, anonymity and potential identification, the level of reporting by the victims and the ensuing reaction from the authorities, all in an attempt to isolate factors that might help with the prevention of cyber bullying. Most of the surveys conducted between 2000 and 2005 investigated middle school students or adolescents as this was the established time frame for the peak of face-to-face bullying and it was assumed to be similar for cyber bullying. Generally speaking, all data indicated a rapid increase in cyber bullying.

As mentioned, the wave of shooting in the 1990's in the US and the subsequent investigation by the FBI recognized the potential risks associated with the use of the Internet for young people. The Department of Justice in Washington DC commissioned a nation-wide study on the dangers of the Internet through the National Center for Missing & Exploited Children (NCMEC). The study of 1,501 young people between the age of 10 and 17 was carried out by the research team of Finkelhor, Mitchell and Wolak during 2000. Their report titled "Online victimization: A Report on the Nations' Youth" focused on sexual material, solicitation and harassment. The insights gained from the study were used to develop education and prevention programs to reduce online risks for young people. These initiatives were possible due to substantial funding which allowed the production of a range of cyber safety materials, the development of Internet protection software and the foundation of cyber safety organisations. With these prevention and intervention programs in place, an identical second survey of again 1,501 young people aged 10 to 17 years was carried out by the same researchers five years later. Despite considerable efforts to combat cyber bullying the problem had not decreased or even stabilised as expected but instead further escalated. From the first study in 2000 to the repeat study in 2005, online harassment had risen from 6% to 9 %. The figures for cyber bullying were even more dramatic, with an increase from 28 % to 48 %, affecting nearly half of all young people between 10 and 17 years of age. The finding that online harassers were

mostly peers and abuse in cyberspace came from prior disputes at school confirmed previously held assumptions and gave a line of attack to battle cyber bullying.

It was now clear that educational institutions, school leadership and individual educators had to handle these knotty matters to work out resolutions to minimise risk. Teachers were starting to undertake professional development about appropriate online behaviour and started devising Acceptable Use Policies (AUP) for computer use and Netiquette guidelines for online activities. These became part of the school repertoire and were issued as policies to attending students and their families. It was accompanied by punishments such as detention and expulsion for inappropriate online behaviour which was an extension of the already existing physical bullying bans and zero-tolerance policies for physical bullying, which school authorities had established. However, cyber incidents were becoming contentious as students argued that online conversations such as emails, chat messages or postings – even if carried out on school computers- were a violation of privacy rights and school authorities had no right to interfere. The complexities increase if cyber bullying came out of the young person's personal bedroom or the privacy of their family lounge room or study but the results of those acts were played out in school with either physical bullying or continued online abuse. At the core of this issue was the tension between an individual's rights to freedom of speech and defamation of a person or their reputation.

Meanwhile, the first ever survey on cyber bullying was conducted in Britain by the National Children's Home (NCH) and published in 2002. The sample size was just half that of the American survey (770 in the UK compared to 1,500 in the US). The age group was also slightly different as the British participants were between 11 and 19 years old while the American participants were between 10 and 17 years old, which makes a cross-studies comparison difficult. However, new insights emerged which was of repeated rather than just one-off incidents of cyber bullying and the victim's familiarity with the bully. In almost three quarter (73 %) of the cases, the cyber bully was a classmate or 'friend', which has significant implications for the approach in tackling the behaviours. Another surprising finding was the occurrence of almost half cyber bullying (48 %) at school or college, which indicated a lack of teacher supervision and either inadequate or outdated Internet filters and blocks at school. It questions schools' ability to provide a safe learning environment and in order to fulfil that responsibility many schools reacted by banning digital devices, introducing a number of policies and setting several punishments such as suspension or expulsion. These measures created a tension between the schools' needs to set boundaries for acceptable speech (that is non-sexist, non-violent, non-racist) and the students' rights to freedom of expression. Shariff (2009) believes that such methods are not fostering positive or respectful learning environments. Instead, a prohibitive and punitive approach creates poisoned and chilled environments that perpetuate cyber-bullying.

Cross-studies comparisons with another UK based investigation were also inhibited by a small sample size (n=92) and yet another variation in the age group (11 to 16 year olds) in the research by Smith, Mahdavi, Carvalho and Tippet (2006). As in the NCH (2002) study, findings indicated that cyber bullying happens both inside and outside of school hours. Findings in both studies challenged previously held assumption that cyber bullying was exclusively occurring outside school hours, although it still held true for the majority of incidents. Cyber bullying at home was explainable due to parents' insufficient technical expertise to install or upgrade protective software and their lack of time to supervise their children's online activities. Nearly

a third (29 %) of young people knew that their parents would disapprove if they knew what they were really doing online (iSafe, 2005).

An astonishing drop in cyber bullying incidents was found by the NCH (2005) for weekends (down to 17 %) and during school holidays (only 6 %). Hanewald (2008) speculated that this which might be due to limited Internet access due to outdoor activities or travel during these times.

Striking were the similarities of the British (NCH, 2002) and American (Finkelhor, Mitchell & Wolak, 2005) teenagers in regard to their silence as about a third of the victims did not tell anyone about the cyber bullying. It might be that they did not recognise the behaviour as cyber bullying, had no one to talk to, where worried that telling an adult about the problem might result in the loss of Internet privileges or that it might make the situation worse for them, especially when at school.

The situation in Canada was investigated during 2005 by two separate scholars, one being Qin Li (2005) who surveyed 177 students in Grade 7 across two schools in Calgary and the other being Robin Kowalski (2007) who investigated 3,700 students in middle school. The latter most significantly found that cyber bullying peaks around the age of 13. Li (2005) discovered that almost 25 % of students having been cyber bullied, which was consistent with the findings in the UK and USA as far as a comparison is possible given the different age and sample size of participants. One marked difference was the unprecedented high (60 %) occurrence of repeated online harassment defined in this study as one to three incidents. Again, varying criteria (two to four, more than three) and time frames (in the last week, last month, last year) make a valid cross-study comparison impossible. A perplexing point of difference was that cyber bullying in chat rooms was the most popular forum in Canada but the least common in Britain.

In terms of the digital environments and tools for cyber bullying, phone calls, text messages and emails were the usual preference. Cyber bullying in chat rooms was the least common (Smith, Mahdavi, Carvalho & Tippet, 2006). In Australia, it was almost opposite with cyber bullying in chat rooms being the second favorite digital environment, second to text messaging followed by email in third place. The sample of Brisbane school children ($n=120$) was recruited in Year 8 (Campbell & Gardner, 2005). Their preference might be a result of more developed key boarding skills by that age, compared to the younger starting age of 11 years for young people in the British study. The high level of technical skills and the necessary equipment (camera to produce still and moving images) might make some forms of cyber bullying less frequent than others. For example impersonation or pretending to be somebody else by taking on their online identity, requiring a high level of technological proficiency. Another explanation might be lower phone charges in the UK compared to Australia, which might make calls and text messages more affordable and thus a more likely tool for cyber bullying.

Studies at that time also found pronounced gender differences in cyber-bullying, for example in an American national representative survey of 935 teenagers, which was conducted over the phone. Compared to only 26 % of boys, 38 % of girls had experienced cyber-bullying. The likelihood of being cyber-bullied was greater for those teenagers who used the Internet daily. Others spreading rumors about them was reported by 13 % of teenagers, especially for those young people who engaged with social networking sites. Only 22 % of young people were harassed online if they did not use social networking sites compared to 39 % of youngster who were active in these. Active users of social networking sites found embarrassing pictures

of themselves online (9%), which were posted without their consent by others (Pew Internet & American Life Project, 2007).

By the mid to late 2000's it was obvious that online environments were difficult to monitor and even more difficult to control. Young people's behavior in physical environments and virtual spaces and the interrelationship of those made the boundaries between the real and virtual worlds fluid and all pervasive. Bullying in physical or virtual spaces "...creates a hostile and negative school environment..." damages students' emotional wellbeing and disrupts learning substantially (Shariff, 2004, p 9). Hence, there was a strong sense of urgency to address these behaviors.

Stage 3: Escalation of Cyber Bullying, Cyber Suicide, Cyber Safety Initiatives and Legislation (Late 2000's)

Cyber bullying was proliferating and intensifying, effective prevention and intervention strategies were lacking and calls for robust legislation amplified by the end of that decade. To a certain extent, this was not surprising as the time spent by young people online had burgeoned.

By the late 2000's young people in Australia aged between 8 and 17 years were spending more than three quarter of an hour (49 minutes) every day on online communication. On average, 18 minutes were used for chatting and messaging which were the most popular online communication forms. An average of 15 minutes per day were used for online games, about a quarter of an hour each day were used for social networking sites (11 minutes) and emailing (5 minutes). The introduction and easy use of Web 2.0 tools meant that 7 % of young people had created their own blog and 13 % had their own website (ACMA, 2008).

In the European Community the time spend online by young people (between 9 and 16 years) is even higher, with an average of 88 minutes per day. The most popular activities were watching YouTube (86%) or communicating via email, social networking sites or Instant messenger (75%). Almost a quarter (23%) of young people blogged, shared files, visited chatrooms or virtual worlds while online (Livingstone, Haddon, Görzig & Ólafsson, 2011).

Similar statistics can be found for the USA where 95 percent of young people (between 12 and 17 years) access the Internet daily (Cowie & Colliety, 2009).

Although it was recognised that many young people used digital devices and Web2.0 applications sensibly, there were some youngsters who took "... advantage of this seemingly unsupervised space as license to say and do what they want" Shariff (2009, p 10). However, these online bullies and cyber bullying had been largely perceived as 'safer' than physical bullying. It was argued that there no physical violence and hence no one got really hurt. The realisation that physical torment online can lead to major emotional and social damage and even real life suicide of young people only just dawned. For example, a survey of 548 Australian teenagers (between 10 and 16 years showed that cyber bullying had a negative effect on act as self-confidence (78%), self-esteem (70 %) and friendship (42%) with peers (Price & Dalgeish, 2010).

Canadian researchers such as Beran and Li (2007) investigated the impact of cyber bullying on 264 students in Year 7 and found that more than half (57%) were angry and 37 % were sad and hurt. "...poor academic performance, school dropout, physical violence, and suicide..." by victims of cyber bullying were identified by Mark and Radcliffe (2011) and corroborated by

Mitchell, Ybarra and Finkelhor (2007) who added alcohol consumption, smoking and depression to the list of problematic behaviours.

Suicides as a result of cyber bullying and bullying in real-life have become so prolife that the term of “bullycide” has been coined (High, n.d.)

One of the most well known cases of cyber suicide is of 13 year old Ryan Patrick Halligan from Vermont, USA who hanged himself (7 October 2003) after being insulted, taunted and threatened for several months. A girl copied and pasted their private conversation in AOL Instant Messenger for his schoolmates to humiliate and embarrass him. Ryan’s case was used by US legislators to propose laws to limit cyber bullying (Associated Press, 2007).

13 year old Megan Meier from Missouri, USA, hanged herself (16 October 2006) after being cyber bullied through the Social Networking Site (SNS) MySpace and MSN Messenger. Megan thought to be in an online relationship with a boy called “Josh Evans” who was actually a fabricated profile by Lori Drew, the mother of one of Megan’s friends. The adult send cruel messages under this disguise and was convicted but later acquitted. The case led to the introduction of the “Megan Meier Cyberbullying Prevention Act” on 22 May 2008 which prohibits harassment over the Internet (Huffstutter, 2007).

Due to those tragic deaths, providing safe online environments had become a high priority for governments, educational authorities, child protection agencies and families themselves. It was thought that filtering and blocking harmful digital materials would protect children and young people form inappropriate contacts and information online and ensure a safe and beneficial experience while engaging with new technologies. Subsequently, computer programs (e.g., Net Nanny, CYBERsitter, Cyberpatrol) to protect young people were created and marketed to parents, schools, public libraries and other relevant organisations. Their functions were varied but mostly pitched at 1.) blocking access to unapproved websites and contacts; 2.) filtering out graphic descriptions or images from approved websites; 3.) blocking personal information from being posted to a worldwide audience; 4.) monitoring the young person’s online activities and 5.) limiting the amount of time spend on the Internet. Software programs such McAfee, Norton or Cyber Sentinel were specifically targeted at parents giving them the option to block or warn of unwanted sites or capturing a screen picture or even force closing the browser. Another feature of parental control software was the detailed report of computer activities either on a daily, weekly or monthly cycle to inform parents which internet sites were visited and when by their children.

However, the futility of the expensive new Internet filter was quickly proven by Tom Wood, a 16-year-old from Melbourne who was able to break through the Australian Government’s \$84.4 million National Filter in only 30 minutes (Higginbottom & Packham, 2007). The National Filter Scheme and various educational pursuits (i.e., a phone help line, online policing, prevention programs) were part of the NetAlert initiative and funded with \$189 million AUD. Despite these efforts to prevent and reduce cyber bullying, incidents have increased, especially since 2006 as report to the NetAlert Helpline confirm (Reachout, 2011).

The worldwide explosion of cyber bullying between 2000 and 2010 is despite considerable amounts of money dedicated to develop Internet filters and blocks and a range of resources to educate on the dangers of online environments. The latter might be explained by a lack of effectiveness as the hotchpotch of – often contradictory - prevention and intervention strategies were never tested for their usefulness. For instance, the advice young people receive ranges from ignoring and deleting cyber bullying message in the hope that the bully will lose interest

to keeping and archiving them to establish a record for future investigations by the authorities to telling an adult about it although it is not clear what implications that might have.

Although governments and various organisations promote anti-bullying and cyber-safety messages and have given generously to establish initiatives such as websites, educational resource kits, online and in-school training programs for teachers, students and parents (NetAlert, 2011; Cybersmart, 2011) there had been no systematic or rigorous investigation of the effectiveness of such measures. The impact of each strategy on various forms of cyber bullying is also unknown as particular forms of abuse may necessitate a more specific response. The lack of empirical data on the value of strategies to combat cyber bullying has been a major problem in eradicating the phenomenon.

Stage 4: Mobile Devices, Wireless Access and Sexting as a New Form of Cyber Bullying (Early 2010's)

The rise of affordable yet powerful mobile devices, a plethora of interactive and user-friendly Web 2.0 applications together with wireless access to the Internet from anywhere brought new variations of cyber bullying. By sharing visuals (still and moving images) on blogs, wikis, bulletin boards, twitter, and social networking sites young people are connecting with their peers. One of these ways of establishing or reaffirming close and intimate connections is through 'sexting', which is the sending or receiving of sexually explicit images via a mobile phone. It can involve teenagers taking semi-nude or completely nude pictures of either themselves or others (such as their girlfriend or boyfriend, a classmate taking shower after physical education class, a peer sun bathing in a secluded space, etc.). The mass media have popularised this behaviour and published photos of partially clothes or unclothed members of the royal family or other celebrities in magazines and newspapers. Film and Sport stars have taken images of themselves and others while intoxicated and in compromising situations and have posted them alongside some commentary on to their twitter or facebook site. The behaviour of these celebrities and role models alongside the general exploration of sexuality and relationships with the opposite or same sex during adolescence are other contributing factors in sexting.

American Research on 10 to 18 year olds (N=4441) indicated that 15.9 % of males (compared to 9.9 % of females) received naked or semi-naked images of someone from their school via a mobile phone (statistically significant $p=.001$), whereas 8.2 % of males (compared to 7.2 % of females) sent them ($p=.021$) to others (Hinduja and Patchin, 2010).

There are currently no reliable statistics on sexting in Australia but the case of a Queensland teenager with a topless photo of a 15-year-old girl on his phone who was charged with possessing child exploitation materials points to its occurrence (Hearn, 2010). The severity of sentence, the punishment of a permanent criminal record but also the consequences such as a loss of potential careers in the law and law enforcement (police, security service), the financial sector (accountancy), education (childcare, school teaching) and so on are affecting young people for the rest of their lives.

Cyber bullying which was understood as limited to peer-to-peer electronic bullying extended now to include cyber bullying of education personnel. Shariff (2009) uses the term of antiauthority cyber expressions to describe cyber bullying of teachers, principals and other school staff. In student-to-student cyber bullying the bully's intention is usually for the victim

to know about the hurtful remarks or upsetting images either directly or through other classmates, who pass on those comments. In contrast, antiauthority cyber expressions are meant to be a private conversation between the student posting them and their classmates. By commenting on educator or educational authorities or by taking pictures or video clips which are unflattering or even modified before posting online, students intent to mock them, 'let off steam' and rebel against their position of power. However, once these messages or images are posted online, there is no control over its distribution. Once the victims are aware of these communications the chances for a productive and harmonious cooperation at school for both are minimal and the potential for legal action regarding slander is given.

Cyber bullying of teachers was investigated by the Ontario College of Teachers (OCT) who gathered data from 1000 Canadian teachers and found that "...cyber-bullying is a widespread phenomenon in the school system." (OCT, 2007:16). Obscene or defamatory online statements from student about teachers were experienced by 84% of the latter. These insults took place in email (45%), chat rooms (44 %), personal websites or blogs (32%), text messaging (32 %), photographs or video clips (19%) and personal voting booth websites (15%). Teachers (8%) viewed disapproval of their appearance or mannerism and clothes as very serious, six percent thought that negative comments about their fairness in grading was very serious and a further five percent viewed malicious gossip as very serious. A fifth of the surveyed teachers (20%) were certain that being cyber bullied by their students would be a cause for either themselves or colleagues leaving the profession.

Without a doubt,

"...cyber-bullying against students, teachers or school officials has a profound impact on the learning of all students, both on and off school property" (Shariff, 2009: 118).

Stage 5: Increase of Legislation and Legal Cases, Mandatory Digital Safety Training (Mid 2010's)

The coming decade will be marked by increasing efforts of risk management that will see an increase in cyber bullying training, policies and compliance requirements. The existing plethora of professional development for teachers (i.e., training, seminars, workshops or conference attendance), resources (i.e., activities, posters, educational kits, videos, sample lessons to teach cyber safety), information (i.e., on website, through journals, newsletters, magazines, books), phone or online help lines or chat forums for affected children, teenagers, families and awareness raising campaigns such as the world-wide anti cyber bullying day will continue. Cyber coaches much like life or health coaches will emerge who advice on the construction of individuals' online activities and reputation and assist with the creation of digital presence.

Research efforts to investigate and trial effective prevention and intervention programs will continue and the gathered evidence will guide policy and practice. It seems feasible that a rating system for digital content might be introduced, similar to the classification used for movies and television programs. Internationally agreed symbols on the rankings of cyber safety might provide guidance on the safety of the online sources and the type of content (i.e., for general exhibition, for mature audience, contains violence and sexual scenes) alongside written and verbal warning to the suitability of the materials.

Mandatory reporting by teachers of students' being maltreatment or exploitation online might be added to the already existence of mandatory reporting of physical and sexual abuse of children. Compulsory training of educators or professionals dealing with young people on aspects of digital citizenships and online safety is envisaged so that they are prepared to deal with the pedagogical challenge of electronic bullying. A legal obligation for professional to report violations of cyber safety against children would send a clear message to perpetrators that their digital activities are recorded and penalized. Also, a national register for electronic perpetrators to monitor or restrict their future online activities is imaginable.

Since cyber bullying is not bound by geographical borders, a global working party or council that serves as an umbrella organization for the numerous national attempts is also conceivable.

CONCLUSION

An in-depth historical commentary would have to consider developments in each countries and the interrelations and overlaps between these occurrences, details which would fill a whole book. Nevertheless, it is hoped that this chapter provided a valuable overview for readers and equips them with sufficient background knowledge for the following chapters.

In summary, cyber bullying is a world-wide, growing problem that has devastating effects for all involved whether they are cyber bullies, victims or bystanders. Protective Internet filtering and blocking software, educational outreach initiatives (i.e., cyber bully awareness raising and behaviour changing programs, free help lines for support) and introduction of legislation to scare and punish online perpetrators are some of the strategies employed to eradicate cyber bullying. Although current initiatives are well intended and heavily funded, they have shown to have no positive impact given the rapid increase of cyber bullying. Hence, investigating effective combat strategies has become imperative in tackling the problem though technological, educational, legislative and policy means on a national as well as a global scale.

Chapter 65

ONLINE SOCIAL NETWORKING BEHAVIOURS, CYBER-BULLYING, MENTAL HEALTH AND BEHAVIOURAL FUNCTIONING IN AUSTRALIAN STUDENTS

Julian J. Dooley* and Adrian J. Scott¹

Sellenger Centre for Research in Law, Justice and Social Change
School of Law and Justice, Edith Cowan University, Australia

ABSTRACT

The present study comprised 599 West Australian students (48.4% male), aged between 12 and 16 years ($M = 13.98$ years, $SD = 0.88$) who participated in a survey relating to technology use, cyber-safety, bullying and cyber-bullying, mental health and behavioural functioning. Students' Social Networking Site (SNS) use was widespread with 61.9% of students using them 6 to 7 days a week. Most of this use occurred on the weekend with 80.2% of students using SNS for one or more hours on an average day on the weekend compared to 58.5% on an average day before or after school and 12.8% on an average day at school. A large proportion (69.8%) of students had 200 or more online friends (49.1% had 300 or more) and 92.0% reported knowing all or nearly all of them in person (35.7% knowing all).

Students who were online (specifically on their SNS) for more time (weekday and weekend) and were younger were more likely to be cyber-bullied. With regard to mental health and behavioural functioning, female students experienced higher levels of depression and anxiety, and more behavioural problems than male students. Students who reported using more SNS and being online for longer over the weekend also experienced higher levels of depression and anxiety, and more behavioural problems. Finally, students who reported being online for longer at school and knowing fewer of their SNS friends in person experienced more behavioural problems.

The results of this study offer important insights into SNS use and behaviours, as well as their impact on cyber-victimisation. They also have significant implications for the way in which young people interact with peers via SNS, for the cyber-bullying behaviours

students might be exposed to, and for the provision of appropriate support and intervention strategies necessary to minimise mental health and behavioural problems.

INTRODUCTION

Communication with others is one of the primary reasons why people use the Internet (Pollet, Roberts and Dunbar, 2011). After all, the Internet is essentially a communication tool – designed to share information with a global audience – that continues to develop and change with the introduction of new technologies (e.g., smartphones). The most notable development in relation to Internet usage over the past decade has been the proliferation of Social Networking Sites (SNS). These sites are built around social connection and are consistently among the most commonly visited sites online (see www.alexacom for latest information on global and national website usage). SNS provide an easy opportunity to communicate with others, connect with groups, organise activities and, ultimately, have some (positive or negative) impact on society (Rainie, Purcell and Smith, 2011).

In the past five years, much has been written describing the demographics of SNS users. Recently, Hampton and colleagues (Hampton, Goulet, Rainie and Purcell, 2011) reported that SNS users in the USA are typically under 35 years of age (although this over-representation of younger users is changing as SNS sites become more widely popular), female, have multiple SNS accounts, have been using the sites for at least a year and use their site several times a day. Similarly, as many as 95% of Australian students in Years 7 to 10 have a SNS profile (de Zwart, Lindsay, Henderson and Phillips, 2011). Currently, the most popular site is Facebook (with nearly one billion active users worldwide) with MySpace, Twitter and LinkedIn also being widely used. These sites may have the largest number of users but they represent a small percentage of the total number of SNS online. There are, for example, SNS aimed at young children, academics, avid travellers, social activists, people with disabilities, artists and musicians to name just a few.

Given the range of SNS available, there are many benefits and opportunities associated with these sites. For example, frequenting these sites can reduce social isolation and increase social support, can promote self-expression and identity development, can promote social engagement and activism, can revive dormant or old relationships and can promote education and knowledge sharing (Hampton et al., 2011; Livingstone and Brake, 2010). Thus, SNS provide opportunities to develop and enhance social relationships as well as build new ones (Lenhart, Madden, Smith, Purcell, Zickuhr and Rainie, 2011).

Although there are numerous benefits to SNS use, there are clearly risks associated with being active on these sites. For example, sharing information on SNS has been associated with an increased risk of online victimisation (e.g., Walrave and Heirman, 2009). This online victimisation is often referred to as cyber-bullying which typically encompasses a complex set of repeated aggressive behaviours intentionally designed to inflict harm on another person through the use of technology (Dooley, Pyzalski and Cross, 2009; Hanewald, 2009). Cyber-bullying is often seen as an extension of offline (or traditional) bullying which has some empirical support (e.g., Gradinger, Strohmeier and Spiel, 2009). However, this approach overlooks important conceptual and functional differences between cyber- and traditional bullying.

For example, while traditional bullying is built on the premise that the behaviour must be repeated (otherwise it is considered aggression, not bullying; see Olweus, 1993), cyber-bullying can easily result from a single action (e.g., posting an embarrassing video online) which can be repeatedly experienced by the person victimised. Furthermore, recent evidence has raised some doubts about the intentionality of cyber-bullying behaviours. For example, Law and colleagues (Law, Shapka, Domene and Gagné, 2012a) reported that the majority of aggressive online messaging by adolescents was 'just kidding around or having fun with friends', with only a small minority perceived as truly intending to 'hurt or embarrass another person'. Additionally, the nature of online exchange can impact on both the delivery and experience of cyber-bullying behaviours. Law and colleagues (Law, Shapka, Hymel, Olson and Waterhouse, 2012b) highlighted important differences between immediate and delayed reinforcement where the awareness of some behaviours (e.g., sending a mean message) may be proximal to the perpetration while others (e.g., building a website) may be more distal. Interestingly, Law and colleagues (Law et al., 2012a) described a similar phenomenon in relation to the perpetration of cyber-bullying whereby adolescents identified themselves with the method of aggression they used (e.g., sending mean messages or creating hostile websites) rather than the role they played (i.e., bully, victim or witness).

These conceptual differences and theoretical challenges have likely contributed to the notable issues related to the measurement of cyber-bullying behaviours. For example, reported prevalence estimates have ranged from 9% to 40% (David-Ferdon and Hertz, 2009; Tokunaga, 2010; Ybarra, Mitchell, Wolak and Finkelhor, 2006). Nevertheless, it is important to note that cyber-bullying rates are almost always lower than traditional bullying rates, with recent USA estimates placing the prevalence of cyber-bullying at 16% compared to 26% for traditional bullying (Kessel Schneider, O'Donnell, Stueve and Coulter, 2012).

Regardless of academic discussions about the conceptual nature of cyber-bullying, there is strong evidence that these experiences can result in significant mental health problems. For example, numerous cross-sectional studies have demonstrated that cyber-bullying is associated with depression (Perren, Dooley, Shaw and Cross, 2010), conduct and emotional problems (Dooley, Gradinger, Strohmeier, Cross and Spiel, 2010; Gradinger, Strohmeier and Spiel, 2009), not feeling safe at school, physical pain, substance misuse, and abuse (Sourander et al., 2010).

Important correlates of the mental health outcomes after cyber-bullying relate to the coping strategies and support networks of the person victimised. Consistently, young people who are victimised are more likely to exhibit psychological ill health if they have ineffective coping strategies or feel unsupported during the experience (Cassidy and Taylor, 2005). An important element of coping is problem-solving style, a pattern of cognitive functioning, which has a significant influence on how people respond to social problems and deal with life stress. For example, ineffective problem-solving styles have been linked with aggressive (e.g., Crick and Dodge, 1999) and bullying behaviours (e.g., Warden and MacKinnon, 2003). Crick and Dodge (1994) also highlighted the importance of peer evaluation and feedback in response to social behaviours and suggested that the more peers support a behaviour, the more likely it is to occur in the future.

In the same vein, the more support provided to victims of bullying, the more positive the mental health outcome. Thus, SNS can offer a potential benefit given the nature and extent of social connection, and result in an immediate source of support if cyber-bullying occurs openly (as is sometimes the case). For example, Dooley and Scott (under review) demonstrated that

mental health problems were more likely to be experienced by young people who were privately victimised (e.g., through text messages or emails) compared to those who were publicly victimised (e.g., through nasty messages or pictures posted on SNS). Although speculative, the authors suggested that the openness of the victimisation might prompt other users to provide support, thus ameliorating mental health problems. Importantly, it is unlikely that support is merely a numbers game where more online friends equals more support. It is more likely that the number of close friends (i.e., those known offline) results in a greater level of support and, as a result, reduced mental health problems.

Ultimately, this issue highlights the complexities associated with SNS use, and the many potential benefits and risks associated with their use. In this chapter, we examine the SNS use of Australian students to determine if there are patterns that predict cyber-victimisation, mental health and behavioural functioning.

METHOD

Participants

A total of 827 students participated in a survey concerning Internet and mobile phone use. All data were collected between November 2011 and March 2012. Students from seven government high schools (out of 11 that were originally contacted) in the metropolitan area of Perth, Western Australia, were recruited to participate in the study. Of the 827 students, 162 (19.6%) were excluded from the current study because they were not active users of SNS, and a further 66 (8.0%) were excluded because they had not completed all relevant sections of the survey. The final sample comprised 599 students, 290 (48.4%) males, aged between 12 and 16 years ($M = 13.98$, $SD = 0.88$).

Students were from Years 8 to 10; with 285 (47.6%) from Year 8, 114 (19.0%) from Year 9, and 198 (33.1%) from Year 10. Two students (0.3%) did not provide their school year. There was little difference in the number of SNS used by students across the three year groups with averages of 2.41 ($SD = 1.04$) for Year 8, 2.65 ($SD = 1.34$) for Year 9 and 2.43 ($SD = 1.11$) for Year 10.

Materials: The survey contained items relating to technology use, cyber-safety practices/strategies, bullying and cyber-bullying, mental health, behavioural functioning, as well as demographic information.

Cyber-bullying. The 11-item Cyber-Victimisation Scale measured students' self-reported experiences of being cyber-bullied. Students indicated on a 5-point Likert scale how often they experienced each of 11 behaviours, which included being sent nasty e-mails or nasty messages on the Internet, having mean or nasty comments posted on websites (e.g., MySpace or Facebook), or being left out or ignored over the Internet. Their responses ranged from 0 'Never' to 4 'Most days this term'.

Mental health. Mental health was assessed using a modified version of the Depression, Anxiety and Stress Scales (DASS; Lovibond and Lovibond, 1995) where only the depression and anxiety scales were used. Responses range from 0 'Does not apply to me' to 3 'Most of the time' and each scale consisted of seven items. Depression (Cronbach's $\alpha = .91$) and anxiety

items (Cronbach's $\alpha = .0.82$) were totalled to produce separate depression and anxiety scores ranging from 0 to 21.

Behavioural functioning. Behaviour problems were assessed using the Strengths and Difficulties Questionnaire (SDQ; Goodman, 2001). The SDQ provides a total difficulties score on the basis of four subscale scores – emotional symptoms, conduct problems, hyperactivity and peer problems – with responses ranging from 0 'Not true' to 2 'Certainly true'. The scores of the 20 items (Cronbach's $\alpha = 0.75$) were totalled to produce a total difficulties score ranging from 0 to 40.

Procedure

The Human Research Ethics Committee of Edith Cowan University and the West Australian Department of Education approved this study. Once schools agreed to participate, information statements and consent forms were delivered two weeks prior to data collection. On the days of data collection, researchers visited the school and, through collaboration with teachers, only students who had agreed to participate in the survey and had signed parental consent forms were provided with the web link for the survey. In almost all cases (96.0%), surveys were completed online. However, paper-and-pencil versions were used in a small number of classes where students either did not have their own laptop or it was not possible to book the school computer laboratory. All students were debriefed about the aims of the study upon completion of the survey.

RESULTS

Regression analyses were performed to assess the impact of nine independent variables (age; number of SNS used; sex; number of days used SNS a week; average number of hours used SNS at school, before and after school and on the weekend; number of SNS friends/contacts; and proportion of SNS friends/contacts known in person) on four dependent variables (exposure to cyber-victimisation; depression and anxiety; and total difficulties). Descriptive statistics for the independent and dependent variables are provided in Tables I and II.

Table I shows that 61.9% of students used SNS 6 to 7 days a week and that most of this use occurred on the weekend: 80.2% of students used SNS for one or more hours on an average day on the weekend compared to 58.5% on an average day before or after school and only 12.8% on an average day at school.

It is also apparent that 69.8% of students had 200 or more SNS friends/contacts, and that 92.0% knew all or nearly all of them in person. With regard to the mental health and behavioural functioning of students, Table II shows that student depression, anxiety and total difficulties scores were low, with average scores of 3.50, 2.72 and 11.28 falling well below the maximum possible scores of 21, 21 and 40 respectively. Finally, just over a quarter (28.9%) of students had been exposed to cyber-victimisation.

Table I. Descriptive Statistics for Social Networking Site users

Variable	<i>M</i>	<i>SD</i>
Age	13.98	0.88
Number of SNS used	2.46	1.23
Variable	<i>n</i>	%
Sex		
Male	290	48.4
Female	309	51.6
Number of days used SNS a week		
1 day a week	28	4.7
2 to 3 days a week	80	13.4
4 to 5 days a week	120	20.0
6 to 7 days a week	371	61.9
Number of hours used SNS at school		
I did not use SNS at school	259	43.2
Less than half an hour	221	36.9
About half an hour	42	7.0
About 1 hour	39	6.5
About 2 hours	14	2.3
About 3 hours	9	1.5
About 4 hours	15	2.5
Number of hours used SNS before and after school		
I did not use SNS before or after school	16	2.7
Less than half an hour	138	23.0
About half an hour	95	15.9
About 1 hour	129	21.5
About 2 hours	101	16.9
About 3 hours	52	8.7
About 4 hours	68	11.4
Number of hours used SNS on the weekend		
I did not use SNS on the weekend	1	0.2
Less than half an hour	61	10.2
About half an hour	53	8.8
About 1 hour	119	19.9
About 2 hours	126	21.0
About 3 hours	94	15.7
About 4 hours	145	24.2
Number of SNS friends/contacts		
0 to 19	8	1.3
20 to 49	18	3.0
50 to 99	35	5.8
100 to 149	59	9.8
150 to 199	61	10.2
200 to 299	124	20.7
300 or more	294	49.1
Proportion of SNS friends/contacts known in person		
None	2	0.3
About half	46	7.7
Nearly all	337	56.3
All	214	35.7

Note. The Depression and Anxiety scores can range from 0 to 21, and the Total difficulties score can range from 0 to 40.

Cyber-bullying: Exposure to cyber-victimisation. Logistic regression (backward method) analysis was performed to assess the impact of the nine independent variables on exposure to cyber-victimisation.

The final model contained four independent variables: average number of hours used SNS on the weekend, age, average number of hours used SNS at school and average number of SNS used. The model was statistically significant, $\chi^2(4, 599) = 49.14, p < .001$, indicating that it was able to distinguish between students who had been exposed to cyber-victimisation and those who had not. The model explained between 7.9% (Cox and Snell R square) and 11.3% (Nagelkerke R square) of the variance in exposure to cyber-victimisation, and correctly classified 71.6% of cases. The B coefficients, standard errors, odds ratios and Wald statistics for the final model of the logistic regression analysis are provided in Table III.

Table II. Descriptive Statistics for Mental health and Behavioural Functioning

Variable	<i>M</i>	<i>SD</i>
Depression score	3.50	4.57
Anxiety score	2.72	3.31
Total difficulties score	11.28	5.91
Variable	<i>n</i>	%
Exposure to cyber-victimisation		
Not exposed	426	71.1
Exposed	173	28.9

Table III. Summary of Logistic Regression Analysis for Exposure to Cyber-Victimisation

Variable	<i>B</i>	<i>SE</i>	Odds ratio	Wald statistic
Number of hours used SNS on the weekend	0.27	0.07	1.32	16.71***
Age	-0.31	0.11	0.74	7.91**
Number of hours used SNS at school	0.15	0.07	1.16	4.49*
Number of SNS used	0.17	0.09	1.18	3.89*

Note. * $p < .05$, ** $p < .01$, *** $p < .001$.

The analysis revealed that students who were exposed to cyber-victimisation used SNS for a greater number of hours on an average day on the weekend and on an average day at school, than students who were not exposed to cyber-victimisation ($p < .001$ and $p < .05$ respectively). Furthermore, students who were exposed to cyber-victimisation used more SNS and were younger than students who were not exposed to cyber-victimisation ($p < .05$ and $p < .01$ respectively).

Mental health: Depression and anxiety. Regression (backward method) analyses were performed to assess the relationship between the nine independent variables and the depression and anxiety scores. The final model for depression contained three independent variables: sex, average number of hours used SNS on the weekend and number of SNS used. The model was statistically significant, $F(3, 595) = 20.37, p < .001$, and explained 8.8% of variance in

depression scores. The final model for anxiety contained the same three independent variables: sex, number of SNS used and average number of hours used SNS on the weekend.

The model was also statistically significant, $F(3, 595) = 12.63, p < .001$, and explained 5.5% of variance in anxiety scores. The B values, standard errors and standardised Beta values (β) for the final models of the regression analyses are provided in Table IV.

Table IV. Regression Analysis Summary for Depression and Anxiety Scores

Variable	B	SEB	β
Depression score			
Sex	1.53	0.37	0.17***
Number of hours used SNS on the weekend	0.46	0.12	0.16***
Number of SNS used	0.47	0.17	0.12**
Anxiety score			
Sex	0.90	0.27	0.14**
Number of SNS used	0.36	0.12	0.12**
Number of hours used SNS on the weekend	0.20	0.09	0.10*

Note. * $p < .05$, ** $p < .01$, *** $p < .001$.

The analyses revealed that female students experienced more depression and anxiety than male students ($p < .001$ and $p < .01$ respectively). Furthermore, the more hours students used SNS on an average day on the weekend, the higher their depression and anxiety scores ($p < .001$ and $p < .05$ respectively); and the more SNS students used, the higher their depression and anxiety scores (both $p < .01$).

Behavioural functioning: Total difficulties. Finally, regression (backward method) analysis was performed to assess the relationship between the nine independent variables and the total difficulties score.

The final model contained five independent variables: number of SNS used, average number of hours used SNS on the weekend, sex, average number of hours used SNS at school and proportion of SNS friends/contacts known in person. The model was statistically significant, $F(5, 593) = 17.36, p < .001$, and explained 12.0% of variance. The B values, standard errors and standardised Beta values (β) for the final model of the regression analysis are provided in Table V.

Table V. Regression Analysis Summary for Total Difficulties Score

Variable	B	SEB	β
Number of SNS used	0.98	0.22	0.19***
Number of hours used SNS on the weekend	0.45	0.15	0.12**
Sex	1.30	0.47	0.11**
Number of hours used SNS at school	0.42	0.18	0.10*
Proportion of SNS friends/contacts known in person	-0.88	0.38	-0.9*

Note. * $p < .05$, ** $p < .01$, *** $p < .001$.

Similar to depression and anxiety, female students experienced more difficulties than male students ($p < .01$); the more hours students used SNS on an average day on the weekend, the

higher their total difficulties scores ($p < .01$); and the more SNS students used, the higher their total difficulties scores ($p < .001$). In addition, the more hours students used SNS on an average day at school, and the less SNS friends/contacts students knew in person, the higher their total difficulties scores (both $p < .05$).

CONCLUSION

SNS are among the most popular online activities, especially for young people. These sites offer many important benefits, such as connecting with friends, developing a social identity, becoming socially conscious and increasing social support (Hampton et al., 2011; Livingstone and Brake, 2010). Although there is tremendous potential to facilitate the provision of support through these sites, there also exists the potential to experience cyber-bullying. However, little is known about the patterns of SNS use and the associated potential for cyber-victimisation. As such, this chapter focused on the experience of cyber-victimisation, mental health and behavioural functioning in SNS users.

In relation to the experience of cyber-victimisation, students who were online (specifically on their SNS) for more time (weekday and weekend) were more likely to be cyber-bullied. In addition, younger students were more likely to be cyber-bullied than older students. These are critically important results associated with basic use factors. Importantly, even though older students had more friends than younger students, the latter were still more at risk of being cyber-bullied. Although it is not possible to know the identity of the perpetrator and their relationship to the victim, this result does raise important questions about the involvement of young people in SNS. Most of the commonly used SNS (e.g., Facebook, Twitter and MySpace) have a minimum age restriction of about 13 years of age. This designation is generally a legal one (websites that collect personal information are not permitted to do so from children under the age of 13 years) although some sites (e.g., Facebook) advocate that this minimum age restriction should be removed. In light of the results of this study, it appears that a reasonable approach to reducing cyber-victimisation would be to increase the minimum age of users. As noted, the primary SNS used by students in this study were Facebook and Twitter.

In addition to the experience of cyber-bullying, students also reported experiencing mental health symptoms and behavioural problems. Specifically, female students reported more symptoms of depression and anxiety than did male students as did students who reported being online for longer over the weekend. Furthermore, the more SNS that students reported using, the higher their self-reported depression and anxiety scores. Consistent with mental health, more behaviour problems were experienced by female students, students who used more SNS and students who used their SNS more on an average day on the weekend. Importantly, the fewer SNS friends students knew in person, the higher their total difficulties scores. Thus, independent of being cyber-bullied, specific SNS use patterns predicted mental and behavioural health problems. This is an important result as the mental health problems that are reported by those students who frequently use SNS are likely to be exacerbated in the event that they are cyber-bullied.

Perren and colleagues (Perren et al., 2010) reported that cyber-bullying resulted in an independent and additive effect on depression symptoms over and above the experience of traditional bullying. While this could be the result of being cyber-bullied, the results of this

study indicate that, at least in part, the impact of SNS use (outside of cyber-bullying) should be considered. The results of this study also provide important insights to the implications of SNS use and the potential impact of being cyber-bullied. The more involved students were in their SNS, the more likely they were to report mental and behavioural health problems.

The recent proliferation of smartphones (i.e., mobile phones that can connect to the Internet) make it easier to engage with SNS and other sites as they can be accessed at any time in any place provided there is an Internet connection available. This ease of connection makes it even more important that students are educated on ways to keep themselves safe as it is not feasible to monitor all of their activities. Thus, early education and the implementation of preventative measures become key strategies to ensure that the benefits of SNS are enhanced while the associated risks are minimised.

Several important results were found in relation to the experience of being cyber-bullied. For example, younger students who used SNS were more likely to be victimised. Dooley and colleagues have previously demonstrated that students with poor coping and social problem solving skills were more likely to avoid proactive help-seeking strategies and to respond aggressively (Dooley et al., 2011, Dooley et al., 2012). Given that social problem skills are considered to develop with age, it is not unreasonable that younger students might respond in socially inappropriate ways (e.g., through bullying or aggression). Given the potential for concurrent mental and behavioural health problems, there is a pressing need for developmentally appropriate preventative approaches to the safe use of SNS.

Furthermore, the more students reported using SNS and the more sites they used, the more likely they were to report being cyber-bullied. Although it is not possible to have a 'safe number' in relation to the number of friends or the amount of time spent online, it is clear that some level of restriction is warranted. The more time spent on a SNS on the weekend and during the week predicted the likelihood of being cyber-bullied. Thus, one protective measure is to limit the amount of time spent online. Given the relationship between extent of use, mental health and behavioural functioning (independent of cyber-bullying), restricting the amount of time spent on SNS is likely to have several benefits. Finally, the relationship between online friends and behavioural health is an important one. It was demonstrated that students who reported having less online friends that were known in person (i.e., offline), had less behaviour problems. Therefore, rather than the number of friends per se being important, it is the number of friends that are known in person that counts.

There are several strengths and limitations of this study. The cross-sectional nature of the study does not make it possible to understand the temporal sequence of SNS use and mental and behavioural health problems. It may be that young people with mental health problems are drawn to using SNS or that SNS use results in symptoms of depression and anxiety. Regardless, the relatively high prevalence and strong predictive associations between SNS use and mental health problems should serve as a strong indicator of the need for preventative mental health messages and support services.

It is not appropriate to wait until cyber-bullying is experienced, and mental health symptoms and behavioural problems occur – these support services should be provided from the outset. Furthermore, the apparent sex differences reported in this study – whereby females reported more mental and behavioural health problems than males – provide a strong argument for sex specific information and support services. However, it is important to note that this could be a legitimate sex-based result or it could be based on an increased likelihood of females to self-report.

The results of this study offer important insights into SNS use and behaviours, as well as their impact on cyber-victimisation. Furthermore, the results have significant implications for the way in which young people interact with peers via SNS, for the cyber-bullying behaviours students' experience, and for the provision of appropriate school-based support and intervention strategies necessary to minimise mental health and behaviour problems.

Of critical importance, the results of this study highlight the need for early preventative approaches to ensure that mental and behavioural health problems are minimised, restrictions are based on the amount of time and level of engagement with SNS, friends are comprised of those known offline and the number of SNS sites used is limited. These key factors represent the greatest opportunity for enhancing the likelihood of a positive experience and reducing the impact of SNS on mental health and behavioural functioning.

ACKNOWLEDGMENTS

The authors would like to thank Eleanor Rudnai, Steffanie Ransom and Luke Fundell-Williamson for their assistance with the data collection. Furthermore, the items on the Cyber-Victimisation Scale were developed in collaboration with colleagues at the Child Health Promotion Research Centre at Edith Cowan University.

Chapter 66

DOES THE CYBERBULLYING PREVENTION PROGRAM SURF-FAIR WORK? AN EVALUATION STUDY

Stephanie Pieschl* and Sina Urbasik

Westfälische Wilhelms-Universität Münster, Germany

ABSTRACT

Recently a plethora of cyberbullying prevention and intervention programs has been proposed; however, empirical evidence for the benefits of these programs is scarce. These programs are derived from distinctly different backgrounds, most are based on conventional anti-bullying programs, target whole schools, and require several weeks of implementation. Surf-Fair (Pieschl and Porsch, 2012) on the other hand focuses exclusively on cyberbullying by capitalizing on (critical) media literacy, targets single classrooms, and can be used for short-term preventions. A corresponding evaluation study presented in this chapter shows that Surf-Fair can be effective in reducing negative cyber incidents, teaching productive coping strategies, and is evaluated positively by participating students. Against the backdrop of the German situation, this chapter further discusses recommendations for schools regarding prevention programs against cyberbullying, considering not only effectiveness, but also fit and feasibility.

INTRODUCTION

In the last couple of years, research all over the world demonstrated that cyberbullying – bullying via internet and mobile phones – is a prevalent problem with negative consequences for adolescents (Görzig, 2011; Smith et al., 2008; Tokunaga, 2010). As a result, multiple prevention and intervention measures have been developed, but empirical evidence regarding their effectiveness is scarce.

This chapter describes the German prevention program Surf-Fair against cyberbullying (for the complete manual in German see Pieschl and Porsch, 2012) and a corresponding evaluation study (Pieschl and Urbasik, 2013).

Cyberbullying in Germany

Since 2005 cyberbullying has been an interdisciplinary research topic in Germany. The reported prevalence of cyberbullying in Germany ranges between 3-35 % for cyber-victimization and between 3-55 % for cyber-bullying (e.g., Görzig, 2011; Katzer, Fetchenhauer, and Belschak, 2009a, 2009b; Pieschl and Porsch, 2012, 2013; Riebel, Jäger, and Fischer, 2009; Schultze-Krumbholz and Scheithauer, 2009; Wachs and Wolf, 2011).

Thus, a substantial fraction of German adolescents is involved in cyberbullying. Additionally, many studies – not only in Germany – show the negative impact of cyberbullying, especially for cyber-victims. Cyber-victims often report emotional distress, sometimes psychological or psycho-somatic symptoms, sometimes changes in behavior, and sometimes they deny negative consequences (e.g., Finkelhor, Mitchell, and Wolak, 2000; Ortega, Elipe, Moran-Merchán, Calmaestra, and Vega, 2009; Patchin and Hinduja, 2006; Staude-Müller, Hansen, and Voss, 2012). To illustrate, cyber-victimization is correlated with low self-esteem, depressive symptoms, suicidal thoughts, drug abuse, and social problems with friends and families (for a summary see Tokunaga, 2010). Cyberbullying can also have far-reaching consequences for young people's future, for example the loss of employment opportunities or scholarships due to legal convictions (e.g., defamation) or participation in documented cyberbullying incidents. Consequently, there is a high demand for effective prevention and intervention.

To create an effective prevention or intervention, it is paramount to consider the relevant social and educational affordances and constraints. In Germany, the individual states are responsible for the educational system and not the federal government. So far none of the states has implemented a state-wide policy or program against cyberbullying. Headmasters or school boards can freely decide if and which programs they wish to implement. Thus, some schools have elaborate and very effective prevention programs against conventional bullying and cyberbullying. Other schools, however, do not even have an explicit policy regarding bullying, and many schools are still searching for adequate measures. Aggravating these issues, it is unclear if schools are responsible for the prevention and intervention of cyberbullying. On the one hand most cyberbullying incidents happen outside of school (Smith et al., 2008), on the other hand cyberbullying affects schools; for instance it is associated with low grades and truancy (Tokunaga, 2010). Another problem is that many teachers – like many adults – feel ill-equipped to address cyberbullying because their media use significantly differs from that of adolescent “digital natives” (Helsper and Eynon, 2010).

Cyberbullying Prevention and Intervention Programs

Currently a plethora of different ideas for the prevention and intervention of cyberbullying floods the German educational market. These can be subdivided into two broad categories (Pieschl and Porsch, 2013)¹:

The first cluster of programs against cyberbullying (Pieschl and Porsch, 2013) is based on the assumption that the effects of programs against conventional bullying should transfer to cyberbullying (Pearce, Cross, Monks, Waters, and Falconer, 2011) because there is a substantial overlap between those adolescents involved in conventional bullying and those involved in cyberbullying (e.g., Katzer, Fetchenhauer, and Belschak, 2009a, 2009b; Riebel et al., 2009; Wachs and Wolf, 2011). Internationally, such programs are often widely implemented whole-school programs spanning multiple weeks and often deal with prevention as well as intervention. Only few of them explicitly address cyberbullying and evaluate the transfer effects regarding cyberbullying, for instance the (Cyber) Friendly Schools program in Australia (Cross et al., 2011) or the Viennese Social Competence training (Spiel and Strohmeier, 2011). Up to now, the only evaluation results which have been published are those regarding the Finnish KiVa program. Through the comparison of students from both experimental and control schools it was shown that KiVa does not only significantly reduce conventional bullying but also cyberbullying (Salmivalli, Kärnä, and Poskiparta, 2011). Even though this approach seems very promising, it is unlikely that such a state-wide program will be implemented in Germany any time soon because of the complex interplay between spheres of responsibility of the federal government, the individual states, and other public bodies (Jäger, Lissmann, and Arbinger, 2010). However, smaller programs against conventional bullying are often implemented in specific schools in Germany, but their effectiveness to reduce cyberbullying has not (yet) been demonstrated.

The second cluster of programs (Pieschl and Porsch, 2013) is based on the assumption that cyberbullying has several unique characteristics in comparison to conventional bullying. These are mostly attributed to the mediated way of communication, namely the potentially public, pervasive, non-deletable, and impoverished nature of online communication (e.g., Dooley, Pyżalski, and Cross, 2009; Mason, 2008; Nocentini et al., 2010; Pieschl and Porsch, 2012, 2013; Smith et al., 2008; Tokunaga, 2010). Such programs specifically target cyberbullying and are often based on theories of media literacy and media education as well as foundations of conventional bullying. In Germany, only few of these programs provide information about their theoretical background or didactical approach and even fewer provide information about their effectiveness. To illustrate, theatre pedagogic approaches are often implemented in Germany (“r@ausgemobbt”, see www.comic-on.de, or “click it! 2”, see www.zartbitter.de) and many brochures and websites with information about media literacy, data safety, and cyberbullying are publicly available (e.g., www.klicksafe.de). Only recently, two evidence-based programs of this kind have been published: Preliminary results regarding the program “media heroes” (Schultze-Krumbholz, Zagorscak, Siebenbrock, and Scheithauer, 2012) indicate that both students and teachers evaluate it positively; results about its effectiveness have not yet been published. The second is our Surf-Fair program described in this chapter (Pieschl and Porsch, 2012).

¹ In this section we only concentrate on prevention and intervention programs against cyberbullying which directly target children and adolescents. We do not address other programs, for example targeting parents.

Evaluating Cyberbullying Prevention Programs

Evaluating cyberbullying prevention programs necessitates the selection of adequate target variables (Pieschl and Porsch, 2013). Most importantly, prevention and intervention programs should reduce cyberbullying. From meta-analyses about the effectiveness of conventional anti-bullying programs we know that effects regarding the reduction of conventional bullying, are mixed: They found partly non-significant, partly positive, and partly negative effects; partly only specific programs have notable effects (Baldry and Farrington, 2007; Merrell, Gueldner, Ross, and Isava, 2008, 2008; Rigby and Slee, 2008; Smith, Schneider, Smith, and Ananiadou, 2004; Ttofi and Farrington, 2011; Vreeman and Carroll, 2007). Transferring these findings to cyberbullying, we expect only small reductions of cyberbullying from corresponding prevention programs, even under ideal conditions. Several issues might further complicate such studies. Cyberbullying can easily happen across classes or schools. As a result, programs might not be able reach all involved adolescents. Furthermore, as cyberbullying is assumed to increase with age (Livingston, Haddon, Görzig, and Ólafsson, 2011; Tokunaga, 2010), prevention programs might only slow down this process. Additionally, it might also be beneficial to evaluate the success of cyberbullying prevention programs regarding other target variables. A meta-analysis of the effects of conventional anti-bullying programs shows more consistent and larger effects regarding knowledge, attitude or self-efficacy (Merrell et al., 2008). For cyberbullying, such variables may include subjective perception of achievement or knowledge about coping strategies.

Regarding the latter, so far no satisfying theoretical model of coping strategies regarding cyberbullying exists and we have no evidence regarding the effectiveness of particular coping strategies (Pieschl and Porsch, 2012, 2013). However, empirical results indicate the existence of different patterns of coping which have also been evaluated by both adolescents and educators. Most adolescents and educators agree that the coping strategies of seeking help and telling someone are promising (Parris, Varjas, Meyers, and Cutts, 2012; Pieschl and Porsch, 2012; Smith et al., 2008; Tokunaga, 2010). They often suggest talking to friends, adults, or the police as a possible solution (Aricak et al., 2008). However, real cyber-victims often tell nobody or only their closest friends of their problem (Dooley, Gradinger, Strohmeier, Cross, and Spiel, 2010; Patchin and Hinduja, 2006; Slonje and Smith, 2008; Wachs and Wolf, 2011). Technical strategies such as blocking within a specific internet application are also recommended by the majority of adolescents and educators (Diamanduros, Downs, and Jenkins, 2008; Pieschl and Porsch, 2012; Riebel et al., 2009; Smith et al., 2008). These strategies are often also employed by real cyber-victims (Aricak et al., 2008). On the other hand, avoidance or withdrawal strategies that ignore the problem might be recommended by and implemented by adolescents (Dehue, Bolman, and Völlink, 2008; Parris et al., 2012; Patchin and Hinduja, 2006; Smith et al., 2008), but these strategies can only be productive for infrequent incidents (Pieschl and Porsch, 2012). Even less desirable strategies of retaliation (Pieschl and Porsch, 2012; Riebel et al., 2009) are often recommended by adolescents (Dehue et al., 2008; Smith et al., 2008). Data on the strong correlation between cyber-bullying and cyber-victimization (Livingston et al., 2011; Schultze-Krumbholz and Scheithauer, 2009) indicates that this strategy might be employed frequently by real cyber-victims, but generally leads to an escalation of the situation. To conclude, the current consensus between adolescents and researchers is that no ideal coping strategy solution for cyberbullying is known (Parris et al., 2012; Pieschl and Porsch, 2012, 2013; Smith et al., 2008). However, some coping strategies seem more promising than others.

This pattern of promising coping strategies could be fostered by successful prevention programs.

SURF-FAIR

We reacted to this overall situation by developing and evaluating the relatively short cyberbullying prevention program Surf-Fair (Pieschl and Porsch, 2012). Surf-Fair can be implemented by teachers into their 5th-7th grade classrooms or it can be used in youth groups and can be adapted to other age groups. It possesses a sound theoretical and empirical foundation.

A Constructivist Didactic Approach

Surf-Fair is grounded in the constructivist didactic approach of anchored instruction (CTGV, 1992). Within this approach, an authentic and complex everyday-life problem is presented without a solution as an anchor for learning and transfer. Subsequently, learners identify and define the problems within this example and actively find useful solutions. Teachers support this process by moderating the group process. This approach has been successful in diverse contexts (e.g., Bottge, Rueda, Serlin, Hung, and Kwon, 2007; CTGV, 1992; Shyu, 1999).

We transferred the approach of anchored instruction to the prevention of cyberbullying (Pieschl and Porsch, 2012). We confronted students with a fictitious but authentic everyday example of cyberbullying via a short video (“Cyberbullying against Max”; 9 minutes). The protagonist Max experiences an escalating series of cyberbullying incidents. A false social network profile about him is created including insults, rumors, and a distorted photo. An embarrassing video of Max is uploaded on an internet video portal and mean comments are posted on this site. Max receives many anonymous insults and threats via the internet and on his mobile phone. Soon he feels desperate, helpless, and tries to avoid his computer altogether. His feelings are visualized by a thickening label on his forehead (“idiot”). The end of the video shows the whole class where most students seem unhappy. Many students have labels on their foreheads (cyber-victims) and/or dirty hands (cyber-bullies).

The subsequent Surf-Fair exercises (Pieschl and Porsch, 2012) deal with different aspects of this authentic case. All exercises have the same underlying rationale. Students are the active constructors of their own knowledge; their opinions and knowledge are the focal point in the exercises. Teachers therefore do not have to be experts regarding internet applications or cyberbullying. Their task is to encourage students to define the problem, find solutions, and critically and ethically reflect their own media use. As in reality, there is no “ideal” solution to solve the complex problem of cyberbullying. The modular Surf-Fair exercises can be specifically selected and freely combined to focus on particular aspects of cyberbullying. Some exercises focus on the social nature of cyberbullying in general and consequently show the importance of not only targeting cyber-victims and cyber-bullies but also cyber-bystanders (Salmivalli, 1999). Cyber-bystanders are the most prevalent group of adolescents involved in cyberbullying in Germany (mpfs, 2011). Depending on their behavior they can help to sustain

(assistants or reinforcers of the cyber-bully; outsiders who stay silent) or stop cyberbullying (defenders of the cyber-victim) (Salmivalli, 1999). Therefore, this group of adolescents is a very promising target for the prevention and intervention of cyberbullying. Other exercises focus on one specific perspective and stimulate critical reflection on what can be done from that perspective to prevent cyberbullying and/or to alleviate its negative consequences.

Two Examples of Surf-Fair Exercises

The exercise “diary” (module 5; Pieschl and Porsch, 2012) introduces the relevant social roles for sustaining cyberbullying. By actively taking different roles, students learn perspective taking and empathy. Consequently, they should use this knowledge to critically and ethically reflect their own media use. After watching the video “Cyberbullying against Max”, students are subdivided into three groups according to three main characters in the video: cyber-victims, cyber-bullies, and cyber-bystanders. Each student has to compose a diary entry from the assigned perspective which explicitly focuses on behavior, cognition, and emotion. The teacher collects all diary entries and randomly reads a minimum of two entries from each perspective. Here are some extracts of what real students wrote: “I did not know what to do, everyone acted anonymously on the internet. I felt very bad because it was really mean to spread these rumors about me – and everybody could read it.” (cyber-victim). “I wanted to be cool. I just bullied Max because nobody likes him, anyway. It was mean, but it was worth it!” (cyber-bully). “I would have loved to help Max, but I did not want to become the next victim.” (cyber-bystander). The most important thoughts and feelings of each character are collected on the blackboard and discussed. Several points can be made: Cyberbullying happens in cyberspace but has consequences for the real life of everybody involved, for example for their emotional wellbeing. At least at the end of the video nobody is happy with the situation, not even the cyber-bully. Cyberbullying does not only concern cyber-bullies and cyber-victims but also cyber-bystanders. This exercise does not focus on potential solutions; therefore it is necessary to follow up with additional exercises.

One exercise that focuses mostly on cyber-victims is called “ballast” (module 8; Pieschl and Porsch, 2012). Students learn about the consequences of cyberbullying from the perspective of the cyber-victim. They can explore their own idiosyncratic threshold of pain regarding cyber incidents. Something that hurts one adolescent a lot might not bother another at all. Furthermore, students discuss different coping strategies for cyberbullying, especially the strategy of help-seeking and sharing emotional distress. In the first part of the exercise, the whole class is confronted with multiple cyber incidents, some from the video, some potentially very harmful, others ambiguous or harmless. Each student got three signaling cards. The red card indicates “totally unacceptable”, the green card indicates “totally acceptable”, and the yellow card indicates “somewhat acceptable, somewhat unacceptable”. For each incident the whole class takes a vote. Then the students discuss their reasons, and the results are recorded on the blackboard. After each incident, real stones are selected, their weight corresponding to the degree that the incident would distress students. One volunteer is needed. This volunteer dresses in a large jacket with big pockets. The selected stones are placed in the volunteer’s jacket. In the second part of the exercise, the volunteer is asked how s/he feels and usually s/he says “totally depressed” (because of the stones’ weight). Students have to come up with promising coping strategies for distressing incidents (figuratively: how to get rid of the stones’

weight). Several different kinds of strategies should be discussed. If the cyber-victim tells someone about a distressing cyber incident that kind of sharing is usually relieving (figuratively: distribute the stones to everyone the volunteer tells about incidents). However, some of the cyber incidents leave cyber traces on the internet, such as ugly photos, embarrassing videos, or nasty comments. Accordingly, students also should discuss strategies to delete these traces, for example how to report someone to the internet service providers. All coping strategies that students come up with are noted on a blackboard and discussed. It is important that students do not endorse nonproductive strategies such as retaliation (potential escalation) or ignorance (potential continuation behind one's back). Therefore, students should be stimulated to critically evaluate the (long-term) consequences of each coping strategy; if students do not realize potentially negative consequences, teachers can help by leading the discussion in a productive direction.

Teaching Media Literacy

These examples demonstrate that Surf-Fair does not focus on conventional bullying. It focuses exclusively on cyberbullying and the specific characteristics of mediated communication (Pieschl and Porsch, 2012). As a theoretical framework we refer to the conceptualization of media literacy of Dieter Baacke (1996), a German educational scientist. He differentiates media critique, media knowledge, media use, and media creation as facets of media literacy. Surf-Fair most explicitly targets students' *media critique* (also see Parris et al., 2012). Students should learn that mediated communication entails real humans as communication partners even though they generally cannot see them; and that personal data once on the internet is hard to erase. Students should apply this knowledge to themselves, for example, by critically reflecting which personal information to post on the internet. Students should act socially acceptable on the internet, for instance by applying the same ethical standards to mediated communication as to face-to-face communication. Consequently, the risk of being cyber-victimized should be reduced, for example by posting less personal information on the internet, and the risk of cyber-bullying should be reduced, for example because potential perpetrators are aware of the consequences for their targets and because cyber-bystanders refuse to act as assistants or reinforcers instead defending cyber-victims.

HYPOTHESES

We conducted a quasi-experimental study (Pieschl and Urbasik, 2013) to evaluate the effectiveness of Surf-Fair and tested the following hypotheses: (1) Surf-Fair reduces the prevalence of negative cyber incidents. (2) Surf-Fair enhances the propensity of using adequate coping strategies (proactive and technical strategies) and it reduces the propensity of using inadequate coping strategies (retaliation and withdrawal) in case of cyber-victimization. (3) Students evaluate their learning gain from Surf-Fair positively. All effects are dependent on the dose of treatment; more treatment results in more pronounced effects.

METHOD

Procedure

Three 6th grade classrooms of a German grammar school participated in this study. The school decided which class was assigned to which treatment. One class received no treatment and served as the control group (CG), one class received a short one-period treatment of 90 minutes (EX90) and the third class received a long treatment of 180 minutes in two 90-minute periods in two consecutive weeks (EX180). The treatments were administered by the second author. All students filled-out three questionnaires. One was administered before the treatment (pre), one directly after the treatment (post), and the last one was completed approximately two months after the treatment (follow-up). These questionnaires contained, among others², questions about the prevalence of potentially harmful cyber incidents in the last two months (pre and follow-up), questions about the propensity to use different patterns coping strategies (pre, post, and follow-up), and self-rated achievement (post and follow-up in the experimental groups). Thus, Surf-Fair was evaluated in a pre-post-follow-up quasi-experimental design.

Sample

The three participating classes encompass $N = 97$ students. Parental consent was obtained for all students. However, due to some students' absence during parts of the study only $n = 87$ students participated in the complete prevention program and completed all three questionnaires. In the remainder of this chapter we will focus exclusively on these students. The three classes (each $n = 29$) did not differ significantly in age ($F(2, 84) = .093, p = .911$); across all classes students were $M = 11.41$ ($SD = .60$) years old. The classes also did not differ significantly in gender distribution ($\chi^2(2) = 3.346, p = .188$); across all classes 39 boys (45 %) and 48 girls (55 %) participated in this study. All of them reported having access to the internet at home (100 %) and almost all reported owning a mobile phone (91 %). They self-rated their competence (moderately) high regarding the use of the internet ($M = 4.02, SD = .90$) and the use of their mobile phones ($M = 4.16, SD = 1.23$), both on a scale from 1 = "low" to 5 = "high".

Material

Cyberbullying Prevention Program Surf-Fair

Only an essential fraction of all Surf-Fair exercises was used in this study (Pieschl and Porsch, 2012); in the EX180 class these exercises were supplemented with additional exercises not in the manual. The official Surf-Fair modules are referred to by their module numbers.

The EX90 class saw the open-ended film about a fictitious cyberbullying case and in the subsequent discussion students learned about the definition of cyberbullying (module 4: "Cyberbullying against Max"). Then, students wrote diary entries about feelings, thoughts, and

² These questionnaires contained more parts than reported in this chapter. We report only the information relevant for our stated hypotheses. The non-reported parts of the questionnaires further address students' media use, their knowledge and attitude towards cyberbullying, and their experience of negative offline incidents.

behaviors of the cyber-victim, cyber-perpetrator, and cyber-bystander in the film and discussed these (module 5: “diary”). Finally, fictitious cyberbullying situations were presented, evaluated regarding their level of distress, and various coping strategies were discussed, for example help-seeking (module 8: “ballast”). More information about these exercises can be found in the previous description of Surf-Fair.

The EX180 class’ treatment consisted of two 90-minutes sessions in two consecutive weeks. Session 1 consisted of modules 4 and 5 (see EX90 treatment). Additionally, face-to-face communication and computer-mediated communication were compared via a fictitious chat scenario and students learned about netiquette. In session 2, students filled-in personal profiles for a fictitious social networking site and learned what they revealed about themselves (module 9: “profile”). Then they completed module 8 (see EX90 treatment). Additionally, German laws relevant for cyberbullying were discussed with fictitious examples.

Demographics and Self-Rated Achievement

In the pre-questionnaire students had to report their age, gender, technical equipment (internet access and mobile phone ownership) as well as rate their competence regarding the internet and mobile phone use on a scale from 1 = “low” to 5 = “high” (see sample description). In the post- and follow-up questionnaires, students in the experimental classes had to rate their achievement regarding the cyberbullying prevention program with the item “I have learned a lot in the anti-cyberbullying program.” on a scale from 1 = “not true at all” to 5 = “definitely true”.

Cyber Incident Prevalence

We adapted the cyberbullying questionnaire of Riebel et al. (2009) to now include the following five of Willard’s (2007) categories: harassment, denigration, impersonation, outing, and exclusion³. A definition of cyberbullying was given including the criteria of repetition, power imbalance, and intent to harm (Dooley et al., 2009). Students were then asked how often these five categories of incidents happened to them in the last two months. Answers could be given on a 5-point scale with the categories “never”, “once or twice”, “several times a month”, “about once a week”, and “several times a week”. Parallel questions were asked first for cyber-victimization and subsequently for cyber-bullying. To illustrate, for cyber-victimization by harassment students answered the question “How often did someone send you a threat or insult via the internet or via mobile phone?”. If students always answered “never” they were automatically categorized as “no cyber-target” or “no cyber-perpetrator”. If they gave at least once a different answer they were automatically categorized as “cyber-target” or “cyber-perpetrator”. Please note that we do not refer to these categories as “cyberbullying”. We considered all negative cyber incidents regardless of the defining characteristics of cyberbullying. The rationale behind this is that Surf-Fair targets the reduction of all potentially harmful cyber behaviors or incidents.

³ We excluded the following of Willard’s (2007) categories on purpose: “Flaming” is defined as a “heated, short-lived argument” (p. 5) but the involved adolescents are assumed to be of similar power. Therefore this does not constitute cyberbullying. The additional categories of “cyberstalking” and “cyberthreats” were excluded because we subsumed the relevant aspects of these categories – the less severe forms – under the category of harassment. The more severe forms on the other hand would also not be labeled bullying in the face-to-face context and therefore we also did not include them in cyberspace.

Coping with Cyber-Victimization

Students were asked to imagine that they had been a victim of cyberbullying. They received a list of twelve potential coping strategies (partly adapted from Riebel et al., 2009). For each of these strategies they had to indicate the probability of using this strategy on a 5-point scale ranging from 1 = “definitely not” to 5 = “definitely”. In order to find a meaningful factor solution we ran an exploratory factor analysis across all classes and across all three questionnaires. One item had to be excluded because it did not rate significantly on any dimension. The final solution has four meaningful dimensions (see Table 1).

Table 1. The results of the exploratory factor analysis regarding coping strategies

	Factor 1 withdrawal	Factor 1 technical	Factor 2 retaliation	Factor 3 proactive
I change my account.	.66			
I switch off my computer.	.63			
I try to avoid him.	.56			
I report him to the ISP.		.78		
I block him in the application.		.72		
I insult him.			.92	
I bully him.			.67	
I threaten to beat him up.			.61	
I report the incident to an adult.				.70
I go to the police.				.43
I ask him to stop.				.27
Cronbach's Alpha	.64	.72	.71	.49

Note. Exploratory factor analysis with principal axis factor extraction and oblique rotation; this solution explains 49.84 % of variance. Factor loadings < .25 are not reported in this table. ISP = Internet Service Provider.

The reliability of the factors “withdrawal”, “technical”, and “retaliation” was acceptable (Cronbach's $\alpha > .60$). The reliability of the factor “proactive” was unacceptably low, therefore the results regarding this factor have to be interpreted with due caution.

RESULTS

Descriptive Results across the Whole Sample

Across all three classes approximately 20 % of students were classified as cyber-targets and between 13-16 % as cyber-perpetrators (see Table 2). Furthermore, on average students

initially (pre) reported they would use proactive, withdrawal and technical coping, but were not likely to use retaliation coping.

Table 2. Descriptives of the dependent variables across all classes

	pre	post	follow-up
cyber-target	<i>n</i> = 17 (19.50 %)	-	<i>n</i> = 18 (20.90 %)
cyber-perpetrator	<i>n</i> = 14 (16.10 %)	-	<i>n</i> = 11 (12.60 %)
withdrawal coping*	3.31 (1.07)	3.42 (.98)	3.32 (1.08)
technical coping*	3.15 (1.13)	3.76 (1.17)	3.63 (1.25)
retaliation coping*	1.52 (.67)	1.67 (.86)	1.77 (.93)
proactive coping*	3.34 (.84)	3.47 (.84)	3.33 (.91)
self-rated achievement**	-	4.43 (.70)	4.21 (1.03)

Note. All descriptive reported in this table are computed across all experimental groups unless otherwise indicated (*n* = 87). The columns indicate different questionnaires at different times of treatment (pre, post, and follow-up). * In these rows the mean and standard deviations (in brackets) are given, all on scales from 1 = “definitely not” to 5 = “definitely”. **In this row the mean and standard deviations (in brackets) of students’ answers to the question “I have learned a lot in the anti-cyberbullying program.” with the answer options 1 = “is not true at all” to 5 = “is definitely true” are given. Only students in the two treatment groups answered this question (*n* = 58).

The general pattern did not change over time, but at the follow-up questionnaire students most strongly indicated they would use technical coping, followed by proactive and withdrawal coping (see Table 2). Furthermore, students in the treatment classes reported that they learned a lot from the prevention program Surf-Fair (see Table 2). These means were significantly higher than the neutral midpoint of the scale (= 3) at the time of post-treatment ($t(57) = 15.49$, $p < .001$) and at the time of follow-up ($t(56) = 8.87$, $p < .001$).

Effects of the Cyberbullying Prevention Program Surf-Fair

Cyber Incident Prevalence

To determine if the (different doses of the) cyberbullying prevention program Surf-Fair had effects on the prevalence of cyber incidents, we computed two binomial logistic regressions (method: enter), one for cyber-target prevalence and one for cyber-perpetrator prevalence. The respective prevalence at the follow-up-questionnaire was the criterion, the respective prevalence at the pre-questionnaire and the dummy-coded treatment groups (CG, EX90, and EX180) were the predictors.

For cyber-target prevalence, the regression model is significantly superior to the default model and it explains 35 % of variance. Both, the cyber-target prevalence indicated by the pre-questionnaire and the treatment groups were significant predictors, with the comparison between the control group (CG) and the group with the long treatment (EX180) being significant as well (see Table 3). The prevalence of cyber target incidents increased in the

control group (CG), stayed approximately the same in the short treatment group (EX90), and decreased in the long treatment group (EX180; see Figure 1).

Table 3. Logistic regression analysis regarding cyber-target prevalence (follow-up)

Predictor	β	SE β	Wald X^2	df	p	e^{β} (odds ratio)
constant	-2.461	.521	22.291	1	.000	.085
cyber-target (pre)	2.503	.800	9.796	1	.002	12.214
treatment (TR)			7.808	2	.020	
TR (1) (CG vs. EX180)	-2.122	.785	7.307	1	.007	.120
TR (2) (CG vs. EX90)	.743	.499	2.213	1	.137	2.101

Note. Nagelkerke $R^2 = .350$. Regression model: $X^2(3) = 21.881$, $p < .001$.

Figure 1. Cyber-target prevalence by treatment group (X-axis) and measurement time (black and white columns).

For cyber-perpetrator prevalence, the regression model is significantly superior to the default model and it explains 41 % of variance. The cyber-perpetrator prevalence indicated by the pre-questionnaire is a significant predictor; furthermore, the comparison between the control group (CG) and the group with the long treatment (EX180) is significant (see Table 4).

The prevalence of cyber perpetrator incidents increased in the control group (CG), stayed the same in the short treatment group (EX90), and decreased in the long treatment group (EX180; see Figure 2).

Table 4. Logistic regression analysis regarding cyber-perpetrator prevalence (follow-up)

Predictor	β	SE β	Wald X^2	df	p	e^{β} (odds ratio)
constant	-3.271	.626	27.326	1	.000	.038
cyber-perpetrator (pre)	3.244	.859	14.260	1	.000	25.636
treatment (TR)			3.951	2	.139	
TR (1) (CG vs. EX180)	-1.604	.813	3.893	1	.048	.201
TR (2) (CG vs. EX90)	.835	.571	2.141	1	.143	2.305

Note. Nagelkerke $R^2 = .411$. Regression model: $X^2(3) = 21.447$, $p < .001$.

Figure 2. Cyber-perpetrator prevalence by treatment group (X-axis) and measurement time (black and white columns).

Coping with Cyber-Victimization

To determine if the (different doses of the) cyberbullying prevention program Surf-Fair had effects on the propensity to use different kinds of coping strategies in case of cyber-victimization we computed repeated-measure ANOVAs with the three questionnaires as the within-subject repeated-measure factor (pre, post, and follow-up) and the three treatment groups as between-subject factor (CG, EX90, and EX180). We computed separate ANOVAS for different dimensions of coping (withdrawal, technical, retaliation, and proactive).

We found no significant main or interaction effects for the coping strategies of withdrawal or proactive coping. The propensity to use these strategies did not change significantly over time and did not significantly differ between treatment groups.

For technical coping we found a significant main effect of the repeated-measure factor ($F(2, 80) = 12.739$, $p < .001$, $\eta_p^2 = .242$) and a significant main effect of the treatment ($F(2, 81) = 4.876$, $p = .010$, $\eta_p^2 = .107$); however, we did not find a significant interaction ($F(4, 162) = 1.015$, $p = .401$). The propensity to use this strategy increased significantly from before (pre)

to after (post) the treatment and it also increased with higher doses of treatment ($CG < EX90 < EX180$; see Figure 3).

Figure 3. Propensity to use technical coping by measurement time (X-axis; main effect) and by treatment group (different lines; main effect).

For the retaliation coping strategy we found a significant main effect of the repeated-measure factor ($F(2, 80) = 6.249, p = .003, \eta_p^2 = .135$), but no significant main effect of the treatment ($F(2, 81) = 2.310, p = .106$) and no significant interaction ($F(4, 162) = 1.431, p = .226$). The propensity to use this strategy increased significantly from before (pre) to after (post) the treatment. Plotting the different treatment groups (without Figure) indicates that students in the long treatment class (EX180) reported equally likely use of this strategy across time, but students in the control (CG) and short treatment (EX90) class reported more likely use of this strategy at later points of time.

Self-Rated Achievement

To determine if the (different doses of the) cyberbullying prevention program Surf-Fair had effects on students' self-rated achievement we computed a repeated-measure ANOVA with the two questionnaires after the treatment as the within-subject repeated-measure factor (post and follow-up) and the three treatment groups as between-subject factor (CG, EX90, and EX180).

We found a significant main effect of the treatment ($F(1, 55) = 4.699, p = .035, \eta_p^2 = .079$), but no significant effect of the repeated-measure factor ($F(1, 55) = 3.521, p = .066$) and no significant interaction ($F(1, 55) = .001, p = .974$). Students in the long treatment class (EX180) consistently evaluated their achievement more positively (post: $M = .64, SD = .49$; follow-up: $M = 4.43, SD = .84$) than students in the short treatment class (EX90: post: $M = 4.21, SD = .82$; follow-up: $M = 4.00, SD = 1.17$).

CONCLUSION

The Effectiveness of Surf-Fair

We confirmed our first hypothesis that (1) Surf-Fair reduces the prevalence of negative cyber incidents. The prevalence of negative cyber incidents approximately two months after the treatment was significantly predicted by the treatment groups. For cyber-target and cyber-perpetrator incidents, the contrast between the control group and the long treatment group was significant. While the prevalence of negative cyber incidents increased in the control group, it stayed approximately on the same level in the short treatment group and decreased in the long treatment group. These effects appear to be related to the dose of treatment: More treatment was associated with more pronounced effects. However, we also consider the short treatment a (partial) success because we did not observe an increase of negative cyber incidents as seen in the control group. Against the backdrop of the mixed effects regarding conventional anti-bullying programs, these results can be evaluated as excellent.

We partly confirmed and had to partly reject our second hypothesis that (2) Surf-Fair enhances the propensity of using adequate coping strategies (proactive and technical strategies) and it reduces the propensity of using inadequate coping strategies (retaliation and withdrawal) in case of cyber-victimization. We found affirmative results for technical coping, contradictory results for retaliation coping, and no significant effects regarding proactive coping or withdrawal. First, we have to consider that students do not seem to share our categorization of adequate and inadequate coping strategies. Across all classes, students report a high propensity of using proactive, technical, and withdrawal strategies and a low propensity of using retaliation strategies. Students seem to consider withdrawal a productive strategy. One potential explanation might be that students applied an inclusive definition of cyberbullying, including single negative cyber incidents. In such cases, withdrawal might be a productive strategy. We might not have found significant effects regarding withdrawal because students' opinions might not have been systematically refuted by Surf-Fair exercises. One reason for not finding any effect for proactive coping might be this factor's low reliability. The factor consists of three diverse items, namely "tell an adult", "go to the police", and "tell to stop". These facets might not have been equally addressed by Surf-Fair. For retaliation we found a significant main effect of time. Across all classes students were more likely to use retaliation after the treatment than before. Even though the treatment had no significant effect, we know that the increase of retaliation is especially due to the control class, followed by the short treatment class. One potential explanation is that it is very easy to retaliate in cyberspace. If adolescents are cyber-victimized and do not effectively regulate their emotions, revenge might seem like a productive and satisfying solution (see Polzer, Stodt, and Brand, 2011). For technical coping we found main effects of time and treatment. After the treatment students reported a higher propensity of using technical coping strategies in case of cyber-victimization. This effect was dependent on the dose of treatment; more treatment resulted in higher likelihood of using technical coping. This effect is in line with our hypothesis.

We confirmed our third hypothesis that (3) Students evaluate their learning gain from Surf-Fair positively. Furthermore, this effect was dependent on the dose of treatment; more treatment resulted in higher self-rated achievement.

To summarize (Pieschl and Urbasik, 2013), these results demonstrate that students evaluate their learning gain from Surf-Fair very positively, that students are more likely to use technical coping strategies after participating in Surf-Fair, and most importantly that students were less likely to be involved in negative cyber incidents after participating in Surf-Fair. This shows that even short programs exclusively focusing on cyberbullying can be effective.

Limitations, Theoretical and Practical Implications

The evaluation study presented in this chapter (Pieschl and Urbasik, 2013) is only an exploratory study regarding the effectiveness of Surf-Fair. There are several limitations. This study has a relatively small sample size and the sample was drawn from a German grammar school, the highest academic track in the three-tier German school system. Additionally, not all Surf-Fair exercises were implemented and we did not test for the effects of specific exercises. Therefore, we do not know if these results can be transferred to other populations or other compositions of Surf-Fair. Furthermore, the sample was not randomly distributed to the experimental groups – the study is a quasi-experiment. Consequently, a number of potential confounding variables might have biased the final results. These disadvantages of field research are partly compensated by its advantages. For example, we investigated an ecologically valid sample of students in the target context. Surf-Fair was developed for implementation in 5-7th grade classrooms. The only deviation from the manual was that the second author administered Surf-Fair instead of the teachers themselves.

Despite these limitations these results have several implications (Pieschl and Urbasik, 2013). On the theoretical side these results imply that cyberbullying has cyber-specific characteristics that can be adequate starting points for effective prevention. Surf-Fair exclusively addresses cyberbullying and its foundation is predominantly based on media literacy rather than conventional bullying. The presented results show that such a program can be effective. However, conventional anti-bullying programs like KiVa also can cause a reduction of cyberbullying (Salmivalli et al., 2011). Together, these results imply that there might indeed be a large intersection of conventional bullying and cyberbullying – but also unique characteristics of both kinds of bullying. Tackling the problem of cyberbullying from both or from either of these directions seems promising (Pieschl and Porsch, 2013; Pieschl and Urbasik, 2013).

There are also several practical implications for schools, especially for countries such as Germany where schools can self-select any anti-(cyber-)bullying policy or program (Pieschl and Porsch, 2012, 2013; Pieschl and Urbasik, 2013). At the current state of research it is impossible to give final evidence-based advice to schools. Only a few evaluation studies have been published about the effectiveness of prevention and intervention programs against cyberbullying. These results indicate that programs with a wide range of theoretical backgrounds can potentially reduce cyberbullying and that the effectiveness of cyberbullying prevention programs can be systematically evaluated (see above). First, schools should select programs with empirical indicators of their effectiveness. However, more practical consideration regarding feasibility and fit are also important such as: Who will administer the treatment (teachers vs. professionals)? How much (teaching) time can be spent on the treatment? What are the predominant problems in the specific school or youth group, a general lack of social competence or cyberbullying? Secondly, schools should select programs that fit

their specific problems and are feasible in their specific context. Programs such as Surf-Fair can only be successful if students already possess a certain level of social competence and if face-to-face problems are not the main reason for cyberbullying. Programs against conventional bullying should take precedence wherever necessary. If these programs do not explicitly address the cyber-specific aspects of cyberbullying, we recommend complementary programs such as Surf-Fair. Even such very short media literacy interventions can have significant effects.

ACKNOWLEDGMENTS

The evaluation study reported in this chapter was part of the second author's Diploma thesis. Furthermore, another German paper about this study has been submitted (Pieschl and Urbasik, 2013). The description of the didactic approach and the exercises of Surf-Fair were translated from the German manual (Pieschl and Porsch, 2012). We thank Torsten Porsch, Ricarda Moll, Stefanie Nordenbrock, and Moritz Desinger for their comments on the first draft of this chapter.

ABSTRACT

This chapter addresses three central questions relevant to school-based cyber bullying prevention programs for high schools. The first question is whether and how cyber bullying differs from traditional bullying behavior among teenagers. With ongoing increases in youths' use of electronic and Internet-based technology to communicate socially, cyber bullying has emerged as a new form of peer aggression and bullying behavior (Raskauskas and Stoltz, 2007). However, what is less clear is whether it is a new and distinct "form" of bullying or whether it is simply social bullying in cyber space. The second question is whether schools have the authority and responsibility to prevent behavior that occurs off-campus (Willard, 2007a), a concern that raises important legal issues and implications for prevention. The third question speaks to the central theme of the chapter, that is, what can high schools do to prevent cyber bullying? To the extent that cyber bullying is similar to other forms of bullying, programs to prevent bullying among adolescents should be equally effective in preventing cyber bullying.

To address this question, we will review current programming for high school aged youth. Additionally, data from a larger study of bullying behaviors are used to examine the prevalence of cyber bullying as well as the effects of different bullying prevention approaches on levels of cyber bullying and victimization in 14 U.S. high schools during a two-year period. We will conclude this chapter by discussing potential future directions for programs and policies aimed at preventing cyber bullying in high school populations.

INTRODUCTION

In recent years, Internet and electronic social communication have increased substantially among high-school aged youth worldwide. Studies have shown high and growing levels of use among teenagers in the United States (Lenhart, Purcell, Smith, and Zickuhr, 2010), Canada (Li, 2008), the United Kingdom (Slonje and Smith, 2008), Australia (Cross et al., 2009), East Asia (Jung, Kim, Lin, and Cheong, 2005), and the Netherlands (van den Eijnden, Meerkerk, Vermulst, Spijkerman, and Engels, 2008). On the one hand, social interactions in cyberspace can afford youth new opportunities for positive social engagement, including friendship, social expression, and social support (Gross, 2004; Snakenborg, Van Acker, and Gable, 2011). On the other hand, electronic communication can also provide a venue for negative and harmful social interactions. Of particular concern is cyber bullying, defined as repeated acts of aggression intended to harm, exclude, or embarrass others delivered through mobile phone or Internet-based technologies, such as through e-mail, chat rooms, blogs, social networking sites, and instant and/or text messaging (Patchin and Hinduja, 2006; Williams and Guerra, 2007).

Prevalence rates for cyber bullying and victimization among youth vary across studies. For example, Juvonen and Gross (2008) found that 72% of U.S. adolescents reported experiencing cyber victimization at least once in their lifetime when it was defined as someone “saying mean things” over the Internet. Other studies with adolescent samples have reported rates ranging from approximately 10% (Williams and Guerra, 2007) to 50% (Raskauskas and Stoltz, 2007) of youth who have been victims of cyber bullying over the past year. Across studies, findings suggest that 20% to 40% of youth experience cyber victimization (Tokunaga, 2010). These rates are similar to or slightly less than those reported in large-scale studies of youth involvement in non-electronic, “traditional” forms of physical and verbal bullying or victimization (Nansel et al., 2001; Ybarra, Boyd, Korchmaros, and Oppenheim, 2012).

Cyber bullying has been associated with a range of negative psychosocial outcomes, particularly for victims (Snakenborg et al., 2011; Ybarra and Mitchell, 2004a; Ybarra and Mitchell, 2004b). For example, youth who report being victims of cyber bullying are significantly more likely than non-victims to concurrently report depressive symptomatology, social anxiety, lower levels of self-esteem, and harassing others online themselves (Tokunaga, 2010). Cyber victimization has been related to emotional distress, anger, and sadness (Patchin and Hinduja, 2006; Topçu, Erdur-Barker, and Capa-Aydin, 2008; Ybarra, 2004). In some cases, the consequences are life-altering, such as in the recent cases of teen suicide stemming from repeated online harassment and victimization (Tokunaga, 2010).

Given the increased use of electronic communication among youth, relatively high rates of cyber bullying, and potentially devastating consequences for victims, there has been a surge of interest in how to best prevent cyber bullying during the teenage years. A related issue is what institutions or agencies should be the primary venue for preventive interventions. Schools are an obvious choice because teenagers spend a considerable amount of time there (Juvonen and Gross, 2008; Mason, 2008). However, because cyber bullying primarily occurs in out-of-school contexts, there is concern about schools’ authority to intervene (Willard, 2007a).

This chapter addresses three issues related to preventing cyber bullying in high schools. First, we consider whether and how cyber bullying differs from traditional forms of bullying. A central question is whether it is a new and distinct form of bullying, or whether it is simply social bullying in cyberspace. Next, we discuss whether high schools have the authority and

responsibility to prevent behavior that occurs off-campus. This raises important legal issues, including schools' ability to regulate free speech, their role in regulating non-school behavior, and their responsibility to provide a safe environment for students by addressing behaviors that may compromise student safety (Snakenborg et al., 2011; Willard, 2007a).

Third, we review what high schools can do to prevent cyber bullying. To the extent that cyber bullying is the same as other forms of bullying and shares common risk factors, programs to prevent bullying among adolescents should be equally effective in preventing cyber bullying. We review high school bullying prevention programs, focusing on programs that have examined the impact of general bullying prevention efforts on cyber bullying or have targeted cyber bullying specifically. Additionally, we present original data from a large-scale bullying prevention study in 14 U.S. high schools (Williams and Guerra, 2007). We conclude by discussing future directions for programs and policies aimed at preventing cyber bullying in high schools.

IS CYBER BULLYING A DISTINCT FORM OF BULLYING?

Definitions of bullying typically include repeated acts of aggression intended to harm others that involve a real or perceived power imbalance (Olweus, 1993). In the case of cyber bullying, the intent to harm others is clear, and a power imbalance may be inferred based on the "power" of electronic media to reach beyond a small group of youth. Although cyber bullying does not directly cause physical harm, it can include a threat of harm. In most cases, it is similar to indirect forms of bullying such as gossiping, excluding others, or saying mean things behind someone's back (Chibbaro, 2007; Underwood and Rosen, 2010).

What differentiates cyber bullying from non-electronic forms is the means by which it occurs—by definition it is bullying delivered through mobile phone or Internet-based technologies, such as through e-mail, chat rooms, blogs, social networking sites, and instant and/or text messaging (Patchin and Hinduja, 2006). This creates a multitude of options and diversity of forms. It may occur through individual or combined modes of communication (e-mail, instant message, chat room, blog posts, social networking profile, text or picture message, etc.) and through various methods or types of victimization, such as outing and trickery (tricking someone into disclosing personal information and then telling others), happy slapping (video recording and sharing acts of physical aggression), and masquerading or impersonating others (Willard, 2007b).

Cyber bullying also eliminates direct confrontation of victims. Given that cyber bullies are not engaging in face-to-face interactions with their victims, they may be removed from the impact of their actions on victims (e.g., emotional cues and distress), which in turn may have a disinhibiting effect that increases bullying (Hinduja and Patchin, 2008). The anonymity that comes with electronic communication also can amplify behavioral disinhibition (Underwood and Rosen, 2010; Ybarra and Mitchell, 2004b). As a result of this anonymity, cyber bullies may experience fewer social consequences, such as disapproval and/or punishment (Willard, 2007a).

Cyber victims also are more readily accessible than victims of traditional bullying behavior (Patchin and Hinduja, 2008; Tokunaga, 2010). Victimization can occur at any hour of the day, across a variety of contexts, so that victims may be harassed even when at home—unlike many

forms of traditional bullying. Victims are less likely to report this “hidden” form of bullying. For example, Juvonen and Gross (2008) found that 90% of youth between the ages of 12 and 17 said that they would not tell adults about cyber bullying, with younger teens (ages 12-14) being more likely to say that they do not report instances to parents for fear of losing Internet privileges.

Although cyber bullying appears to be a distinct form of bullying, it is unclear whether prevention programs for general bullying still can be effective. An important question is whether the causes and correlates of bullying and victimization differ between cyber bullying and general bullying. In terms of age trends, both cyber bullying and traditional bullying increase significantly in middle school (Tokunaga, 2010). However, whereas traditional bullying decreases in high school, some studies have demonstrated that cyber bullying appears to increase (Hinduja and Patchin, 2008; Raskauskas and Stoltz, 2007; Ybarra and Mitchell, 2004a). Unlike traditional bullying, with males being more likely to engage in direct, physical bullying and females being more likely to use indirect (social or relational) bullying, cyberbullying seems to be equally divided between males and females (Nansel et al., 2001; Tokunkaga, 2010).

Still, youth who engage in traditional bullying are more likely to engage in cyber bullying—cyber bullying and victimization are highly correlated with other forms of bullying and victimization during adolescence (Gradinger, Strohmeier, and Spiel, 2009; Jose, Kljakovic, Scheib, and Notter, 2012; Wang, Iannotti, and Nansel, 2009). Cyber bullying perpetration and victimization also appear to share risk and protective factors with more traditional forms of bullying throughout childhood and adolescence (Hemphill et al., 2012; Juvonen and Gross, 2008; Williams and Guerra, 2007). This suggests that at least some common psychological and contextual underpinnings can be targeted by broad-based and comprehensive preventive interventions, although it may be necessary to additionally address the unique dynamics of cyber bullying for adolescents.

DO SCHOOLS HAVE THE AUTHORITY AND RESPONSIBILITY TO INTERVENE?

There is a general consensus that schools should act to regulate cyber bullying behavior through laws, policies, and practices (Juvonen and Gross, 2008; Mason, 2008; Raskauskas and Stoltz, 2007; Snakenborg et al., 2011). However, because cyber bullying typically occurs outside of school grounds, this is not a simple task (Draa and Sydney, 2009). Schools’ authority to regulate students’ off-campus freedom of speech and behavior, as well as their responsibility for the safety of their students, present important issues that have been raised in the context of school-based cyber bullying prevention. *Authority* refers to the legally justified right to impose formal discipline. *Responsibility* refers to the legal obligation of the schools to protect students (Willard, 2007a), although it remains unclear as to whether schools can be held responsible for cyber bullying that occurs between students when the actions are committed outside of school, on a student’s private computer.

The most frequently used legal standard is the *Tinker* standard (drawn from *Tinker v. Des Moines Independent Community School District*, 1969), which holds that school officials have the legal authority to respond to off-campus student speech if that speech has caused, or could

cause, a substantial disruption on campus or interfere with the rights of students to receive an education and/or remain safe (Willard, 2010). Other legal proceedings have upheld this standard, but its application to specific cyber bullying cases may be difficult, as the effects of materials posted on the Internet or exchanged between students may vary substantially in the extent to which different situations or cases of cyber bullying disrupt on-campus learning or the school climate. For example, Mason (2008) has reviewed several recent legal cases that have come to different resolutions with regard to the regulation of off-campus speech and its impact on the school setting, sometimes ruling in the offending students' favor (e.g., *Killion v. Franklin Regular District*, 2001). Although a specific review of recent U.S. case law is outside the scope of this chapter, it is important to note that in cases of school authority to intervene, schools must provide ample evidence that the cyber bullying case in question disrupts daily school learning and students' perceptions of the school climate, and in some situations involves threats against a specific person (Mason, 2008).

There is a growing body of research to support this position. Studies have found that victims who are cyber bullied are more likely to retaliate at school (Juvonen and Gross, 2008). Other studies have demonstrated that students who are bullied at school are more likely to be a victim of cyber bullying off-campus (e.g., Hinduja and Patchin, 2008), indicating a bidirectional relationship between on- and off-campus traditional and cyber bullying behavior. Cyber bullying also has been found to have serious consequences on youths' general school-based functioning. Victims of cyber bullying have been found to report increased academic problems in their school-related achievement (Beran and Li, 2007), higher rates of truancy (Katzner, Fetschenhauer, and Belschack, 2009), and feelings that school is an unsafe place (Varjas, Henrich, and Meyers, 2009).

Beran and Li (2007) and Patchin and Hinduja (2006) suggest that observed declines in academic functioning might be attributed to poor concentration and higher levels of stress as a result of cyber victimization experiences, emphasizing the relationship between out-of-school cyber bullying and in-school consequences. Other studies have also demonstrated substantial school-based risks associated with off-campus cyber bullying. For example, Ybarra, Diener-West, and Leaf (2007) found that students who were harassed by others online were eight times more likely than non-harassed peers to concurrently carry a weapon to school, and were also more likely to skip school and report more school disciplinary problems.

As a result of growing concerns around cyber safety and the issue of schools' responsibility to intervene, school districts in the U.S. have developed a range of prevention and intervention strategies to address cyber (as well as other) bullying behaviors. The Protecting Children in the 21st Century Act, passed by the U.S. Congress in 2008 and including legislation pertaining to cyber bullying protection, has been an impetus for state-by-state legislation related to this issue, although some states had specific legislation as early as 2006 (National Conference of State Legislatures, 2010; Snakenborg et al., 2011).

Currently, of the 50 U.S. states, 34 have enacted legislation in an attempt to regulate and control cyber bullying and cyber threats in schools. These laws contain provisions for school districts to control the impact of cyber bullying in learning environments. States that do not contain specific cyber bullying legislation (Alaska, Arizona, Colorado, Indiana, Maine, Montana, North Dakota, Utah, and Wisconsin) do have comprehensive bullying or anti-harassment statutes that include harassment by electronic methods. The remaining 7 states (Hawaii, Louisiana, Missouri, Ohio, South Dakota, Texas, and Vermont) have pending

legislation that include cyber bullying within the broad definition of bullying, meaning school districts must adopt policies for the prevention of and education about all forms of bullying.

School personnel in the U.S. and elsewhere should be aware of their district policies and current legislation related to cyber bullying behavior (Draa and Sydney, 2009; Mason, 2008). Further, disciplinary actions related to cyber bullying—whether on or off campus—should be handled carefully, as some efforts may result in greater harm to the students being targeted. Asking for legal guidance is recommended in such cases, as is education for students, teachers, and staff about cyber bullying policies and school-based practices (Kowalski and Limber, 2007). An equally important strategy is to develop broad-based bullying prevention programs for teenagers that are effective in preventing cyber bullying.

INTERVENTIONS TO PREVENT CYBER BULLYING IN HIGH SCHOOL

Given the high degree of overlap between cyber and more traditional forms of bullying, existing school-based bullying prevention programs may be applicable to cyber bullying prevention. However, the majority of bullying prevention and other relevant school-based aggression prevention programs have been primarily developed for and evaluated with elementary or middle school youth, with few programs designed specifically for adolescents (Guerra and Leidy, 2008; Smith, 2010).

Meta-analytic reviews of traditional anti-bullying programs over the last decade have revealed equivocal findings for both program outcomes and the impact of participant age on program effectiveness. Several reviews of school-wide bullying prevention programs have found limited effectiveness, particularly for older youth. For example, Smith, Schneider, Smith, and Ananiadou (2004) reviewed 14 published school-wide bullying program outcome studies and Merrell, Guelder, Ross, and Isava (2008) reviewed 16 published studies. The majority of programs in these reviews were found to have little to no statistically significant effects on self-reports of bullying and victimization, and no differential effects by age of program participants.

In contrast, a more recent meta-analysis by Farrington and Ttofi (2009) in the *Campbell Systematic Reviews* included 44 published and unpublished bullying prevention program evaluations and demonstrated that overall, anti-bullying programs were associated with an average decrease of 20-23% in bullying and 17-20% in victimization. Programs that were more intensive and included parent components, classroom management and disciplinary methods, school-wide policies against bullying, and increased playground supervision had greater reductions in bullying behavior, whereas programs that contained video components, cooperative group work, and disciplinary methods were associated with greater reductions in victimization. Relative to other countries, programs implemented in Norway or Europe showed greater effects compared to programs implemented in Canada and the U.S. Programs seemed to be more effective for children ages 11 and older, although analyses comparing youth in early (11-14) versus late (15-18) adolescence were not included in the review. In general there are fewer program for high school aged youth, and studies that have been conducted show that program effects decline for the older adolescent age group (Smith, 2010).

Most evaluations of traditional anti-bullying programs included in these reviews do not specifically target cyber bullying or measure impact on these behaviors. In part, this is due to the predominance of programs for elementary school children. Given that cyber bullying does

increase during adolescence, beginning with the early adolescent (middle school) years, it is useful to review programs for middle school youth that may be particularly relevant for preventing cyber bullying and/or have specifically examined program impact on this behavior. We focus on four bullying prevention programs that are widely used in schools, have been recommended for cyber bullying prevention (Mason, 2008; Olweus, 2012; Snakenborg et al., 2011), and have been tested among middle school and/or high school youth. These are: (a) the Olweus Bullying Prevention Program; (b) Bully-Proofing Your Schools; (c) the Build Respect: Stop Bullying program; and (d) the KiVa Anti-bullying Program.

The Olweus Bullying Prevention Program (OBPP) is one of the most well-known and widely disseminated bullying prevention programs. The OBPP aims to reduce and prevent bullying through improving the larger school climate, including implementing school rules and consequences around bullying behavior and providing interventions at the whole-school, classroom, individual, and community levels that target interpersonal problem-solving and peer relations (Olweus and Limber, 2010; Olweus, Limber, and Mihalic, 1999). In a recent comprehensive review of quasi-experimental outcome studies in Norway and the U.S., Olweus and Limber (2010) concluded that there is robust evidence for the effectiveness of the OBPP in reducing Norwegian youths' levels of bullying and victimization for elementary school students, but less evidence for effectiveness in the U.S. In non-U.S. samples, program effects have been found for early adolescents in middle school, although U.S.-based studies have not replicated these findings. In general, program effects in the U.S. have been particularly weak among middle and high school age youth (Bauer, Lozano, and Rivara, 2007; Evers, Prochanska, Van Marter, Johnson, and Prochanska, 2007). Although the program also has no published findings on cyber bullying reduction, Olweus (2012) has suggested that the use of evidence-based programing to target traditional bullying should also impact cyber bullying.

Another current school-wide bullying prevention strategy is Bully-Proofing Your Schools (BPYS) (Mason, 2008). BPYS is based upon the OBPP principles. It emphasizes bringing about changes in school climate and norms around bullying behavior through the implementation of school rules and consequences related to bullying (Menard, Grottpeter, Gianola, and O'Neal, 2008). Several experimental and quasi-experimental studies of BPYS in the U.S. demonstrated positive effects of the program on discipline and behavior at the elementary school level (Berkey, Keyes, and Longhurst, 2001; Epstein, Plog, and Porter, 1999), but again, these studies did not show effects for older youth.

The Build Respect, Stop Bullying program is one of few current programs tested among older high school students. Evers, Prochanska, Van Marter, Johnson, and Prochanska (2007) implemented a "transtheoretically-based, tailored" adaptation of this curriculum using three, 30-minute computerized sessions during the school year, along with additional materials about bullying that were provided to staff and parents. The program was tailored according to students' stage of change based on a transtheoretical change model; this model involved decision-making and reinforcement processes designed to assist youth in changing their bullying roles, or behavior (as bully, victim, or bystander). The computerized sessions consisted of text and video testimonials related to bullying and victimization. A sample of 12 middle and 13 high schools were matched and randomized into treatment and control groups, with a total of 1,237 youth in grades 6 through 8 and 1,215 youth in grades 9 through 11 participating in the study. Pre- to posttest analyses revealed a significant reduction at both the middle and high school levels in students reporting bullying and victimization. Although this study did not examine cyber bullying outcomes and has yet to be replicated elsewhere, the computer-based

platform could be promising when applied to cyber bullying prevention for high school students.

The KiVa Anti-bullying Program is one of few school-wide programs that has published effects on cyber bullying outcomes. Developed and evaluated in Finland, “kiva” means “nice” in Finnish and is also an acronym for “Kiusaamista Vastan,” an expression that translates to “against bullying” (Salmivalli, Kärnä, and Poskiparta, 2010). KiVa is grounded in social-cognitive theory, and is based upon research into aggressive children’s social status and the idea that bullying is a whole-group behavior (i.e., bullying contains several participant roles and involves bystander behavior). Consistent with other large-scale bullying programs, the KiVa intervention components are at the school-wide, classroom, and individual level. The components are also developmentally adapted for children ages 7-9, 10-12, and 13-15.

At the universal, or school-wide level, the program aims to increase awareness about bullying as a group process, to promote empathy toward victims, and to teach children how to support victims in bullying situations through classroom-based and school wide initiatives such as increased adult supervision and posters reminding students about bullying policies (Salmivalli et al., 2010). This universal level also contains a computer game for elementary school youth that is modeled upon the classroom lessons and interactively tests knowledge about program-related skills (Kärnä, Voeten, Little, Poskiparta, Kaljonen, et al., 2011). At the individual level, cases of bullying are handled by school staff through discussions between the bully and the victim, and through an intervention designed to increase interactions between the victimized child and more prosocial peers.

A randomized controlled trial of KiVa across 78 middle schools in Finland (grades 4 to 6) with a sample of 8,237 students demonstrated that involvement in the KiVa program was associated with decreased levels of bullying and victimization (Kärnä, Voeten, Little, Poskiparta, Kaljonen, et al., 2011), including reductions in cyber victimization (Salmivalli, Kärnä, and Poskiparta, 2011). This study demonstrated that the KiVa program, which was not specifically targeted at or adapted for cyber bullying, was also effective in reducing cyber bullying at the middle school level. Although this specific study focused on younger children, the overall program has demonstrated effects in a non-randomized trial that included high school youth (Kärnä, Voeten, Little, Poskiparta, Alanen, et al., 2011), making KiVa a promising option for future school-based cyber bullying prevention.

THE PRESENT STUDY

To further test the effectiveness of traditional bullying prevention programs on cyber bullying and cyber victimization among older adolescents in high schools, we report findings from a large-scale, 3-year evaluation of anti-bullying programs in 14 U.S. high schools conducted between 2005 and 2008 in the state of Colorado. Because all schools participating in the study implemented a comprehensive anti-bullying program (i.e., there is no control condition), we are limited to comparing the effectiveness of different types of programs on cyber bullying and victimization outcomes. We also present data on the prevalence of cyber bullying and victimization at the high school level.

METHOD

Overview

Data for the current chapter were collected as part of a larger study, The Bullying Prevention Initiative (BPI), funded by The Colorado Trust, a private, Denver-based grant-making foundation. The BPI provided funding for the implementation of bullying prevention programming in 78 schools, evenly divided between urban and rural settings, across 40 of Colorado's 64 counties. A pretest-posttest survey design was used to collect data from youth in grades 5 (elementary school), 8 (middle school), and 11 (high school) during the fall and spring of 3 academic years (2005-2006, 2006-2007, and 2007-2008). Schools were provided the opportunity to implement a variety of different bullying prevention programs beginning in the second year of the study (2006-2007), which included the OBPP and BPYS, described above. Findings on the prevalence and correlates of both traditional and cyber bullying for the full sample during years 2005-2007 are reported elsewhere (Guerra, Williams, and Sadek; 2011; Williams and Guerra, 2007, 2011). Analyses examining the effects of bullying prevention programming on bullying for this sample have not been previously published. Data reported in this chapter are limited to the high school students in the sample, and include program effects on cyber bullying outcomes.

Participants

A total of 1,276 high school students in grade 11 from 14 different schools (6 rural; 7 urban) participated in the present study from 2006 through 2008. Participants were evenly divided between males (50.7%) and females (49.3%). A majority of the high school subjects self-identified as White, non-Hispanic (57.9%), followed by Hispanic or Latino (33%), or as members of other racial/ethnic groups (9.1% total, consisting of: 2.9% other; 2.3% bi- or multi-racial; 1.5% Native American; 1.5% Asian/Pacific Islander; and 0.9% African American).

Procedures

Data collection procedures for this and the larger sample are detailed elsewhere (e.g., Guerra et al., 2011; Williams and Guerra, 2007, 2011). Briefly, parental consent and participant assent were obtained for all subjects in the current sample in compliance with all relevant Institutional Review Board policies. As mentioned above, data for the present study were collected during the fall and spring for the 2006-2007 and 2007-2008 school years and bullying prevention programs were implemented over this two-year period, beginning in the fall of 2006. Because empirical results were found to be the same during each of the two years of the present study, results from the 2006-2007 and 2007-2008 years were collapsed in the following ways to create a larger high school sample. Prevalence rates for traditional and cyber bullying and victimization are collapsed and reported for the fall of 2006 and 2007. A pretest-posttest design was used to examine the effects of the type of prevention program implemented in the high schools (see below) by collapsing students' reports from the fall of 2006 and 2007 as the pretest

data and the spring of 2007 and 2008 as the posttest data. Similar methods have been used in other studies of these data (e.g., Williams and Guerra, 2007, 2011).

Measures

Traditional and cyber bullying perpetration. Different types of bullying perpetration were measured with four items adapted from Espelage, Holt, and Henkel (2003). Physical bullying was measured by an item that asked whether students “pushed, shoved, tripped, or picked fights with students”; verbal bullying was measured by an item that asked whether students “teased or said mean things to certain students”; social or relational bullying was measured by an item that asked whether students “spread rumors about some students”; and cyber bullying was measured by an item that asked whether students “told lies about some students through email or instant messaging.” Youth were asked whether they had engaged in this behavior “since the school year began” and responses were coded on a 4-point scale ranging from 1-*never*, 2-*one or more times*, 3- *several times*, to 4-*a lot*. Although these items are thought to reference distinct forms of bullying, when the four items are combined they form a reliable bullying perpetration composite measure (Cronbach’s alpha at pretest = .73). Consistent with previous research using these indicators of bullying, the distributions of these items were highly skewed, with a high concentration of participants reporting that they had never perpetrated these types of bullying behaviors. Consequently, each of the four items was dichotomized so that comparisons could be made between participants reporting no perpetration of bullying behavior (a score of 1) and those reporting one or more instances of bullying perpetration (a score of 2-4).

Traditional and cyber victimization. Four items tapping physical, verbal, relational, and cyber victimization were adapted from a victimization scale by Espelage et al. (2003). These items asked whether they had experienced the following over the last school year: “A student or group of students pushed, shoved, tripped, or picked fights with me” (physical victimization); “a student or group of students teased or said mean things to me” (verbal victimization); “a student or group of students spread rumors about me” (social or relational victimization); “a student or group of students told lies about me through email or instant message” (cyber victimization). Responses were coded on a 4-point scale ranging from 1-*never*, 2-*one or more times*, 3- *several times*, to 4-*a lot*, and then dichotomized in the method described above due to the skewed distribution of students reporting no victimization on each of the four items. When combined, these items form a reliable composite measure (Cronbach’s alpha = .84).

Bullying prevention programs. Schools reported the name of their chosen bullying prevention curriculum implemented during the 2006-2007 and 2007-2008 school years. In the larger sample consisting of elementary, middle, and high schools, a majority of schools used either the OBPP or BPYS, both of which were dummy coded with “other” programs (a mix of interventions) as the reference group. In the high school sample, no schools utilized OBPP. However, 5 of the 14 schools used BPYS, with the 9 remaining schools all using a range of different prevention programs. In the current study, participants in schools using BPYS were given a code of 1, whereas participants in schools reporting the use of any other program were given a code of 0, so that effects of a current bullying prevention program designed for younger youth (BPYS; see above section) could be tested against other prevention program efforts.

RESULTS

Analyses focused on (a) examining the prevalence of cyber bullying and victimization relative to traditional bullying and victimization in high schools, and (b) testing the effectiveness of different prevention programs on cyber bullying outcomes. However, as observations related to program effects on cyber bullying outcomes in the study were nested within participants and schools, a condition which typically calls for multi-level modeling, initial 3-level unconditional models were created using Hierarchical Linear Modeling (HLM; Raudenbush, Bryk, Cheong, Congdon, and du Toit, 2011). Three level models included a within persons level, a between persons level, and a between schools level. Results from these models demonstrated that school site accounted for little of the variance in cyber bullying perpetration and victimization outcomes. Given the small amount of variance in cyber bullying accounted for at the between-school level, multi-level modeling was not utilized in any of the subsequent analyses, and all data were collapsed at the individual level and analyzed using Stata version 12.1 (StataCorp, 2011) with standard errors adjusted to account for clustering within schools. Missing data were handled through pairwise deletion, as no pretest demographics (i.e., gender, school site, race/ethnicity) or pretest cyber and traditional bullying or victimization variables were systematically related to missing data at posttest.

Prevalence of traditional and cyber bullying and victimization. Zero-order correlations were run to examine the pretest (fall 2006 and fall 2007) interrelations between physical, verbal, social or relational, and cyber bullying and victimization among high school students. Results showed that all intercorrelations were positive and statistically significant at the .01 level (see Table 1), indicating that multiple forms of both bullying and victimization co-occurred within this sample. Notably, there were moderate correlations between verbal, social, and cyber forms of victimization.

Next, the prevalence of the various forms of bullying and victimization in high schools at the beginning of each academic year within the study were examined. Table 2 shows the percentage of students who endorsed experiencing a particular form of bullying and victimization, as well as gender differences for each form, which were examined through exploratory chi-square tests for independence (with Yates Continuity Corrections). Results demonstrated that overall, cyber bullying and victimization were less prevalent than other forms of bullying, but that 17.1% of youth had perpetrated cyber bullying and 21.5% of youth reported being victimized through electronic means since the beginning of the school year (i.e., immediately prior to the collapsed fall 2006 and fall 2007 pretest data reported here).

Table 1. Zero-Order Correlations Among Pretest Bullying and Victimization Variables

	1	2	3	4	5	6	7
1 Physical Perpetration	--						
2 Verbal Perpetration	.37**	--					
3 Social Perpetration	.18**	.25**	--				
4 Cyber Perpetration	.24**	.25**	.38**	--			
5 Physical Victimization	.28**	.22**	.13**	.12**	--		
6 Verbal Victimization	.16**	.26**	.27**	.13**	.54**	--	
7 Social Victimization	.11**	.20**	.28**	.19**	.38**	.62**	--
8 Cyber Victimization	.15**	.22**	.29**	.34**	.34**	.45**	.51**

** $p < .01$.

There were statistically significant gender differences in the proportion of boys versus girls reporting involvement across all forms of bullying perpetration and victimization. A higher percentage of boys reported perpetrating physical and verbal acts of bullying at least once in the last year, whereas more girls reported perpetrating social and cyber forms of bullying. A higher percentage of boys compared to girls reported physical victimization, but more girls than boys reported verbal, social, and cyber victimization.

Effects of prevention programs on cyber bullying and victimization. Effects of bullying prevention program were analyzed through logistic regressions. Initially, we investigated whether any school-level demographics differences were associated with choice of either the BPYS program (coded as 1; 5 schools total), or any of the other programs used (coded as 0; 9 schools total). Logistic regressions using percent of non-Hispanic White students, percent of student receiving free and reduced lunch, statewide testing scores (reading, writing, and mathematics), urban versus rural location, or student-teacher ratio predicted the binary prevention program outcome. No statistically significant demographics predictors were found, indicating that there were no systematic differences in choice of prevention program according to these school-level demographics variables.

We then examined the effects of BPYS versus other prevention programs on both cyber bullying perpetration and victimization following program implementation, which was the spring of 2007 and spring of 2008 data collection periods collapsed into one posttest time point. Logistic regressions predicting each cyber bullying outcome (bullying perpetration and victimization) were performed, using prevention program as the primary predictor, while controlling for pretest score on the outcome variable, gender, and race/ethnicity. Although preliminary HLM analyses demonstrated that school site accounted for only a small proportion of the variance in the cyber bullying outcome variables, in these analyses we corrected the standard errors for clustering at the school site, similar to procedures used in other studies (e.g., Salmivalli et al., 2011).

Table 2. Prevalence of Different Forms of Bullying and Victimization, and Gender Differences, at Pretest

	Overall	Boys	Girls		
	(%)	(%)	(%)	χ^2	<i>p</i>
Physical Perpetration	25.5	32.6	18.6	30.14	<.001
Verbal Perpetration	57.9	61.2	54.7	5.28	.02
Social Perpetration	22.7	17.8	27.5	15.51	<.001
Cyber Perpetration	17.1	14.7	19.3	4.11	.04
Physical Victimization	31.3	34.4	28.4	4.77	.03
Verbal Victimization	43.9	40.5	47.1	4.91	.03
Social Victimization	43.7	32.4	54.4	56.96	<.001
Cyber Victimization	21.5	15.5	27.2	22.57	<.001

Note. Chi-square statistics are reported with a continuity correction for a 2 by 2 table.

Results are shown in Table 3. The logistic regression for cyber perpetration revealed no statistically significant reductions in this behavior according to prevention program used. Similarly, no results were found for cyber victimization. Findings indicate that use of the BPYS program had no differential effect on cyber bullying or victimization relative to other programs that were implemented in the high schools.

As a result of these null findings, we then examined whether, on average, there was a change in percentage of pretest-to-posttest data for cyber bullying outcomes across schools for the total sample. Percentage calculations showed that both cyber bullying perpetration and victimization increased on average, to 17.5% of the posttest sample reporting cyber bullying perpetration at least once since the beginning of the school year (compared to 17.1% at pretest) and 23.1% of the sample reporting increases in cyber victimization during this period (compared to 21.5% at pretest).

Because the logistic regression model predicting posttest cyber bullying revealed an increased likelihood for cyber bullying perpetration by *males* at posttest (Table 3; $b = .74$, Odds Ratio = 2.11, $p < .001$), unlike the chi-square tests at pretest, we examined gender differences in both cyber bullying perpetration and victimization outcomes at posttest using chi-square tests of independence, with Yates Continuity Corrections.

Table 3. Logistic Regression Results for Cyber Bullying and Victimization Outcomes

	<i>b</i>	<i>SE</i>	<i>p</i>	Odds Ratio	95% CI
Cyber Perpetration Model					
Prevention Program	0.39	0.26	.12	1.48	0.89 – 2.46
Pretest Cyber Perpetration	1.81	0.15	<.001	6.14	4.50 – 8.36
Gender	0.74	0.19	<.001	2.11	1.43 – 3.09
Race	-0.43	0.25	.09	0.65	0.39 – 1.06
Cyber Victimization Model					
Prevention Program	-0.06	0.27	.82	0.93	0.55 – 1.61
Pretest Cyber Victimization	1.56	0.18	<.001	4.76	3.35 – 6.77
Gender	0.20	0.13	.14	1.22	0.95 – 1.58
Race	0.07	0.25	.75	0.93	0.57 – 1.50

Note. Standard errors were adjusted to account for clustering within school site.

Results were in contrast to pretest results, and showed that a greater percentage of males (21.1%) relative to females (14.4%) reported cyber perpetration since the beginning of the school year, $\chi^2(1, n = 812) = 5.892, p = .012$. However, there were no significant gender differences in the proportion of males versus females reporting cyber victimization at posttest, $\chi^2(1, n = 812) = 0.001, p = .969$. These stand in contrast to pretest results, as greater proportion of females reported cyber bullying and victimization relative to males in the pretest data.

DISCUSSION AND LIMITATIONS

This study examined the prevalence rates, gender differences, and impact of school-based prevention program efforts on high school youth in Colorado. Exploratory analyses revealed that cyber bullying and cyber victimization at the beginning of each of the two school years were significantly and positively correlated, and were also positively and statistically significantly correlated with all other forms of traditional bullying (physical, verbal, and social or relational). These findings are similar to previous studies showing a high degree of overlap or correlation between cyber and other forms of bullying behaviors (e.g., Grading et al., 2009;

Wang et al., 2009). Pretest prevalence rates of cyber bullying perpetration (17.1%) and victimization (21.5%) were somewhat lower than traditional bullying behaviors. However, these percentages were within the common range for cyber bullying and victimization across multiple studies (20% to 40%; Tokunaga, 2010). Notably, these percentages are higher than those reported for youth studied in the first wave of the larger BPI study (Williams and Guerra, 2007).

Gender differences for traditional bullying and victimization types were mostly consistent with previous large-scale research (e.g., Nansel et al., 2001), with more boys reporting physical and verbal bullying perpetration and physical victimization, and more girls reporting social perpetration and social and verbal victimization. However, at pretest, a higher proportion of girls were found to report both cyber bullying perpetration and victimization, whereas a higher proportion of boys reported cyber perpetration at posttest, with no gender differences in cyber victimization at pretest.

On average, both cyber bullying and victimization increased at posttest (to 17.5% and 23.1%) in the total sample, with pretest levels of cyber bullying and victimization significantly predicting these outcomes at posttest. In this regard, prevention program implementation did not significantly impact cyber bullying and victimization rates when the BPYS program was compared to a range of other programs used at the high school level. These findings suggest that current school-based prevention programs for high school youth in the U.S. are not effective in preventing cyber bullying. Still, it is important to note that this study was not a controlled effectiveness trial of a specific intervention and did not include a no-treatment control group.

The measures used are also brief, self-report indicators of bullying and victimization. Future research should utilize multi-informant measures with several items to capture the different types of bullying, particularly in the case of cyber bullying and victimization, given the large number of means through which cyber bullying and victimization may occur.

CONCLUSION: FUTURE DIRECTIONS FOR PREVENTING CYBER BULLYING IN HIGH SCHOOLS

Given the limited effectiveness of traditional anti-bullying programs for high school students, and particularly for preventing cyber bullying, it may be necessary to develop programs that (a) specifically target cyber bullying, and (b) identify and impact the causes and correlates of bullying and cyber bullying among adolescents.

In terms of specifically targeted anti-cyber bullying programs, several programs have been developed. These include: (a) The i-SAFE Internet Safety Program (i-SAFE, n.d.) for grades kindergarten through 12; (b) Net Smartz (National Center for Missing and Exploited Children, 2011) for youth up to age 17; and (c) Cyber Bullying: A Prevention Curriculum for Grades 6 Through 12 (Kowalski and Agatston, 2008). These programs offer general information on Internet safety for youth, educators, and parents, as well as more specific information regarding how to identify and appropriately respond to instances of cyber bullying behavior.

For example, the i-SAFE program modules for high school-aged youth contain lessons about protecting one's personal information, how to identify online predators, and the legal or school-based consequences of cyber bullying, whereas the Cyber Bullying curriculum

developed by Kowalski and Agatston (2008) for middle and high school youth includes sessions about creating a more positive cyber space, in addition to educational components related to cyber bullying identification and response techniques. Lessons in these curricula typically are designed for school-based delivery by teachers or other school personnel using interactive scripts for discussion, student activities, and web or video vignettes to facilitate learning (Mason, 2008; Snakenborg et al., 2011).

Although these curricula may be easily integrated into existing school-based prevention programming (Mason, 2008), empirical evaluations of these programs are rare, especially for high school youth. Initial studies suggest that these programs are effective in increasing youths' knowledge of Internet safety in elementary and middle school, although no direct impact on cyber bullying and victimization has been found. Mishna, Cook, Saini, Wu, and McFadden (2009) concluded that changes in knowledge may not be sufficient to reduce cyber bullying perpetration and victimization. In sum, although these cyber-specific programs are promising in their scope and applicability to school-based cyber bullying prevention, more research is needed to determine the effectiveness of these programs, especially for youth in high school.

A particular challenge for high school anti-bullying programs is to understand more fully the dynamics of bullying and victimization across the adolescent years. Qualitative findings from the Colorado BPI study suggest that bullying shifts from a focus on dominance hierarchies in elementary and middle school to competition for sexual partners during high school, and that it becomes an important form of "entertainment" or something to do (Guerra et al., 2011). Cyber bullying can provide an instant and powerful venue for "bringing someone down" (particularly among girls) by insulting, belittling, or circulating explicit and damaging photos and information about someone. The dynamics of school climate, teacher-student interactions, and other school-based conditions may be less relevant for teenage cyber bullying than the dynamics of romantic relationships and social networks. Future anti-bullying programs may need to consider how these shifting relationships impact efforts to prevent both traditional and cyber bullying among high school youth.

APPENDIX A

Author Autobiographies

Ariel A. Williamson, M.A., is a doctoral student in the Clinical Science program at the University of Delaware. She is interested in the implementation and dissemination of intervention programs for adolescent aggressive behavior problems in school, community, and juvenile justice settings.

Beatriz Lucas-Molina, Ph.D., is an associate professor in the department of Educational Sciences at La Rioja University in Spain. Her research interests include bullying and peer harassment in primary and secondary education, school-based violence prevention programs, and family interventions to reduce risk behaviors in children and adolescents.

Nancy G. Guerra, Ed.D., is Professor of Psychology, Associate Provost for International Programs, and Director of the Institute for Global Studies at the University of Delaware. She has published over 100 articles and chapters focused on prevention of aggression and

bullying among children and youth. She currently is the editor of the *Journal of Research on Adolescence* and was a previous associate editor of *Child Development*.

Chapter 68

PROGRESS AND LIMITATIONS IN THE MEASUREMENT OF CYBERBULLYING

Rebecca Dredge^{1,*}, John Gleeson² and Xochitl de la Piedad Garcia³

^{1,2,3}Australian Catholic University, Melbourne

ABSTRACT

To date, the measurement of cyberbullying has been approached inconsistently throughout the research literature. In addition to the myriad of approaches to its measurement, there remains no agreement on a universal definition of cyberbullying. This creates further challenges for its measurement for a number of reasons. Firstly, it is difficult to measure a phenomenon that cannot be easily defined. Secondly, no widely accepted definition within the research literature leads to the development of measures used only in their respective researchers' studies, and finally meaningful cross-study comparisons are problematic. Furthermore, accurately measuring cyberbullying is not only important for empirical research, but also for those working with real life manifestations of this issue across various clinical and educational settings. There appears to be a number of specific problems regarding the measurement of cyberbullying. These include inconsistencies in the measurement of prevalence rates which arise from problems with the construction of questions and problems with the response options provided in cyberbullying measures. Another feature of the measurement of cyberbullying that has varied across published studies is the duration of reference time periods over which participants are asked to recall incidents of cyberbullying. Furthermore, throughout the research on cyberbullying there is a lack of reported psychometric data on respective measures and related constructs. Lastly, differences remain in the specific cyberbullying behaviours or environments that are measured and the overall purpose of the cyberbullying measurement tool. Despite the fact that many of these concerns have been outlined in the traditional bullying measurement research, similar problems remain evident in the cyberbullying measurement research. This book chapter will review each of the above problem areas with a focus on how these issues have developed, affected the measurement of both cyberbullying perpetration and victimisation, and on alternative strategies to the measurement of cyberbullying.

INTRODUCTION

The power of technology is ubiquitous. Every day, new information and communication technologies are implemented by corporations, government agencies, and individuals thereby changing the way people communicate with one another. The positive aspects of internet and mobile technologies should be recognised such as mass mobilisation, real-time communication and widespread access to information, resources and databases. Yet, such technologies also provide new opportunities for individuals to abuse the privilege of technology and use it as a vehicle to harass and bully.

The Definition of Cyberbullying

This type of behaviour has been labelled cyberbullying, a term which implies the extension of traditional bullying to cyberspace. However, different studies have defined cyberbullying in various ways and the lack of consensus has been described as “the most pervasive methodological drawback in cyberbullying research” (Tokunaga, 2010, p. 283). Furthermore, there are a number of different terms that appear to be describing a similar construct and are used interchangeably throughout the literature, without clear definitional differences. This creates a problem of poor discrimination as well as a lack of definitional clarity. Such terms include online harassment (Finkelhor, Mitchell, and Wolak, 2000; Ybarra, Diener-West, and Leaf, 2007), cyberstalking (Alexy, Burgess, Baker, and Smoyak, 2005; Finn, 2004), internet bullying (Williams and Guerra, 2007), cyber aggression (Pornari and Wood, 2010), and electronic bullying (Kowalski and Limber, 2007). Cyberbullying, however, is the most frequently used term in the peer-reviewed research literature and will be used throughout this chapter.

Just as there are many different labels for the same type of behaviour, the label ‘cyberbullying’ is associated with multiple definitions. A selection of cyberbullying definitions are provided in Table 1.

Table 1. Definitions of Cyberbullying Used in the Research Literature

Author (Year)	Cyberbullying Definition
Patchin and Hinduja (2006)	Wilful and repeated harm inflicted through the medium of electronic text (p.152)
Agatston, Kowalski and Limber (2007)	Using the internet to harass and bully others (p. S59)
Kowalski and Limber, 2007	Bullying through e-mail, instant messaging, in a chat room, on a website, or through digital messages or images sent to a cell phone (p. 22)
Smith et al. (2008)	An aggressive, intentional act carried out by a group or individual, using electronic forms of contact, repeatedly and over time against a victim who cannot easily defend him or herself (p. 376)
Slonje and Smith (2008)	Aggression which occurs through modern technological devices, and specifically mobile phones or the internet (p. 147)

The definition of cyberbullying in the research literature has more often consisted of extending the ‘traditional’ definition of bullying to include bullying that occurs in electronic media. In doing so, the most common definitions of cyberbullying include the three basic components of traditional bullying, namely: repetition, power imbalance and deliberate intent to harm (Olweus, 1993). Therefore, in order for behaviour to be considered cyberbullying, it must meet these specific definitional criteria. Smith et al.’s (2008) definition incorporated the three components of traditional bullying and has been used in multiple studies as the preferred cyberbullying definition (Menesini and Nocentini, 2009). Other researchers have detailed specific technologies in their definition as can be seen in Kowalski and Limber’s (2007) definition. This approach to definitional clarity is problematic because future technological advancements will reduce the relevance of these specific modalities of communication. Therefore, there remains a need for an enduring definition that will not require continual revisitation as new technologies emerge (Spears, Slee, Owens, and Johnson, 2009). Moreover, other research has defined cyberbullying very broadly without mentioning specific definitional criteria (e.g., Agatston et al.’s (2007) and Slonje and Smith’s (2008) definitions).

McGrath (2009) noted that due to the variety of “personal, disciplinary, cultural and linguistic factors” (p. 21-22) involved, it may be doubtful that one all inclusive definition can be agreed upon. So, if a unified definition of cyberbullying cannot be constructed, there remains a strong need to create avenues to measure this phenomenon that enable easy comparisons across studies. This means that researchers need to construct measurement tools that produce results that, regardless of the specific definitional criteria measured, can be easily interpreted.

The Measurement of Cyberbullying

The problem with inconsistent definitions is further confounded by an inconsistent approach to measurement. To date, this has been the case with the measurement of cyberbullying throughout the research literature. Without a uniform approach to its measurement, comparisons between the current cyberbullying studies have been extremely difficult.

The main goal of cyberbullying measurement thus far has been to gather prevalence rates of both cyberbullying victimisation and perpetration. This has been assessed mostly by self-report questionnaires and surveys (Tynes, Rose, and Williams, 2010). Others research has included focus groups (Agatston, Kowalski, and Limber, 2007) or interviews (Tynes, 2007) to measure cyberbullying. Some researchers have used traditional bullying questionnaires as a basis for the construction of a measure of cyberbullying (Revised Peer Experiences Questionnaire or the Olweus Bullying Questionnaire) and added cyberbullying related questions onto the already validated measure (Dempsey, Sulkowski, Nichols, and Storch, 2009; Wang, Iannotti, and Nansel, 2009 respectively). Other researchers have developed their own instrument to measure cyberbullying without providing a rationale for its necessity or superiority over others (Tokunaga, 2010); and often without reporting any reliability or validity statistics. There appears to be a number of specific problems regarding the measurement of cyberbullying. These include inconsistencies in the measurement of prevalence rates which arise from problems with the construction of questions and problems with the response options provided for respondents in cyberbullying measures. Another feature of the measurement of cyberbullying that has varied across published studies is the duration of reference time periods

over which participants are asked to recall incidents of cyberbullying. Furthermore, throughout the research on cyberbullying there is a lack of reported psychometric data on measures of cyberbullying and its related constructs. Lastly, differences remain in the sampled cyberbullying behaviours or environments that are measured and the overall purpose of the cyberbullying measurement tool. The above measurement problems have resulted in prevalence rates of cyberbullying victimisation that range from 6% (Finkelhor et al., 2000) to 72% (Juvonen and Gross, 2008) across multiple age groups.

PURPOSE OF THE CYBERBULLYING MEASUREMENT TOOL

As previously mentioned, cyberbullying questionnaires and surveys have overwhelmingly been constructed to measure the prevalence rates of both victimisation and perpetration only. Furthermore, given that research into cyberbullying and its associated constructs is in its early stages, questionnaires typically include a vast number of questions that tackle multiple areas regarding the cyberbullying phenomenon. For example, Li (2010) constructed the 'Cyberbullying Student Survey' and included questions on the respondents' experience of cyberbullying (including reaction, actions after the cyberbullying incident, who the respondent told, and who helped the respondent). The questionnaire also assessed the reasons why individuals become cyberbullies, attitudes towards cyberbullying, witnessing cyberbullying (including frequency of being a witness, response to witnessing cyberbullying, whether or not the respondent would report the cyberbullying and to whom), and opinions about cyberbullying (including how to stop cyberbullying and how the respondent interacts within the online world). Similarly, Smith et al.'s (2008) 'Cyberbullying Questionnaire' included 88 multiple choice questions and two open-ended questions regarding frequency of cyberbullying and victimisation, whether the respondent had heard about cyberbullying occurring in school, the perceived impact of cyberbullying compared to traditional bullying, the number and gender of the cyberbullies, the length of victimisation, who the victim had told, and what the respondent thought may stop cyberbullying from occurring.

Including such extensive and broad data collection should be considered a logical first step in the measurement of a new phenomenon. However, due to the continued development of measurement tools solely used for the respective authors' current study, there has not been a strong enough progression towards the development of tools that identify key variables within cyberbullying to measure. This is a disadvantage for measurement because there is a strong need to systematically investigate variables such as the causes or impact of cyberbullying in greater depth, rather than continuing to follow a purely exploratory approach. Future measurement tools should thoroughly consider the intended outcome(s) of the overall research so that the respective measurement tool can be constructed in such a way as to measure only the variables that are of direct interest instead of including any unnecessary variables.

DIFFERENCES IN MEASURED TECHNOLOGICAL ENVIRONMENTS AND BEHAVIOURS

There are a vast number of forms that cyberbullying can take and environments in which it can occur due to the proliferation and increased sophistication of Computer Mediated

Communication (CMC) and mobile technology. Incidents of cyberbullying traverse numerous media such as e-mail, instant messaging, chat rooms, discussion boards, social networking sites, blogs, text messages, or pictures and videos sent to mobile phones or uploaded onto the internet (Kowlaski, Limber and Agatston, 2008). Hinduja and Patchin (2008) also referred to online environments such as voting/rating websites where visitors to the website can rate a person's physical attractiveness, virtual worlds which are simulated environments where individuals communicate through their avatars, and online gaming.

Arguably these environments should all be included in the measurement of cyberbullying. However, this is not necessarily that straightforward as within each environment, a number of different behaviours can occur. Willard (2007) identified eight forms of cyberbullying including flaming, harassment, denigration, impersonation, outing, trickery, exclusion and cyberstalking. While useful, this taxonomy still does not reference the specific behaviours that occur within CMC and mobile phone technology. Therefore, using these forms when measuring cyberbullying may mean there will be a lack of detail regarding the specific behaviours that technology users engage in. Therefore, another concern regarding previous attempts at developing a measure of cyberbullying has been that measures do not take all forms or behaviours into account (Smith, 2011). More specifically, many questionnaires only ask about certain modalities of CMC such as instant messaging or sending/receiving pictures. For example, Ybarra and Mitchell (2004) asked participants two questions about their experience of online harassment that referred to "rude or nasty comments on the internet" or "using the internet to harass or embarrass someone with whom the youth was mad" (p. 323). Dempsey et al. (2009) made reference to four different cyberbullying behaviours: text message/instant message, comments on web space walls, threatening emails and the creation of a mean or embarrassing web page about the individual. Such research subsequently reports prevalence rates that are only based on a small number of behaviours that fall under the cyberbullying umbrella. Others have sampled a much broader range of behaviours (Akbulut, Sahin and Eristi, 2010; Calvete et al., 2010; Topcu, Erdur-Baker, and Capa-Aydin, 2008) or environments where cyberbullying can occur (Kowalski and Limber, 2007). The difference between these two approaches has an impact not only on prevalence rates, but also on the conceptualisation of cyberbullying in research, educational settings and the media.

The difficulty of including all cyberbullying behaviours in one measurement tool is obvious considering the ever-changing technological environments that continue to become available. To allow measurement tools to keep up to date with these changes and to measure environments and behaviours that are relevant to the populations in which they are being measured, constant attention needs to be paid to the current state of technology and how it is being used. To limit the scope of this task, surveys/ questionnaires could focus solely on one technological environment (e.g., chatrooms, social networking sites) or one area of enquiry (e.g., impact of cyberbullying victimisation, coping strategies used to deal with cyberbullying victimisation). This means that measurement tools will measure each variable rigorously and in sufficient detail so that each feature of the phenomenon of cyberbullying can be understood accurately. This will subsequently aid in the development of targeted and relevant interventions for the population being assessed.

Inconsistencies in the Measurement of Prevalence Rates

As the focus of cyberbullying research has been on the prevalence rates of either victimisation or perpetration, it is important to identify the meaning of the term ‘prevalence’. Solberg and Olweus (2003) focused on the epidemiological definition of prevalence when translating prevalence into the area of traditional bullying in schools. They referred to prevalence as:

The proportion or percentage of students in a school or other meaningful unit who have been exposed to bullying/victimizing behaviour by other students with some defined frequency within a specified time period in the group of interest. (p. 240)

Solberg and Olweus (2003) noted however, that there is significant variability in prevalence rates across studies for multiple reasons, some of which defy the above definition of prevalence. These reasons include: reliance on different data sources, the presence or absence of a definition of bullying, different time frames or reference periods used, variability in response or rating categories, and the use of single items to measure prevalence versus composite scores or scales. Despite the fact that these concerns have been outlined in the traditional bullying measurement research, similar problems are evident in the cyberbullying measurement research. The elements that contribute to the reporting of inconsistent, variable prevalence rates will be discussed below.

PROBLEMS WITH THE CONSTRUCTION OF QUESTIONS IN CYBERBULLYING MEASURES

Definition

In their report for the Internet Safety Technical Task Force, auspiced by the Multi-State Working Group on Social Networking of State Attorneys General of the United States, Schrock and Boyd (2008) noted that the differences in the wording used to operationalise questions in different studies may explain the wide disparity in reported cyberbullying rates. The researchers pointed out that the reported differences in cyberbullying rates are especially evident when some questionnaires included a detailed definition of cyberbullying and others did not. For example, at the beginning of his survey, Li (2010) provided a paragraph long definition of cyberbullying and then proceeded to ask participants (Grade 7-12 students), based on the definition provided, “how often have you been cyberbullied?” or “how often have you cyberbullied others?” (p.388). Other studies also provided definitions of cyberbullying referencing specific mobile phone and online behaviours and criteria to meet the definition of cyberbullying (Beran and Li, 2005; Menesini, Nocentini and Calussi, 2010; Ortega, Elipe, Mora-Merchán, Calmaestra, and Vega, 2009; Patchin and Hinduja, 2006), while others provided no extra information or definition of the construct they intended to measure (Akbulut, et al., 2010; Calvete, Orue, Estevez, Villardon and Padilla, 2010; Topcu and Erdur-Baker, 2010; Tynes et al., 2010).

There appears to be a number of concerns that arise when analysing those questionnaires which provide participants with a definition of cyberbullying as a reference point to structure their answers, and those that do not. Firstly, as previously mentioned, there is not a universal

definition of cyberbullying. Therefore, most questionnaires that do provide a definition before any ensuing questionnaire items provide different definitions. For example, the cyberbullying definition Menesini et al.'s (2010) used in their cyberbullying measurement tool clearly referred to the three pillars of the traditional bullying definition: repetition, power imbalance and intent. However, Patchin and Hinduja (2006) provided a definition of cyberbullying that highlighted the importance of repetition and intent, but did not refer to a power imbalance. Not only is the lack of consistency in presented definitional criteria a concern for future meaningful cross-study comparisons, but it also creates a challenge for the respondent to respond to the questionnaire items accurately (Tokunaga, 2010).

Furthermore, Li (2010) did not provide his participants with a definition of cyberbullying, but he did provide a list of behaviour-based experiences that were examples of cyberbullying. However, none of these experiences referred to any of the above listed essential features of a cyberbullying definition. Ybarra (2009) conducted a systematic literature review of research papers on cyberbullying published between 1999 and 2008. Of the 14 studies reviewed, half of the studies provided a definition of cyberbullying. Ybarra compared the prevalence rates of the studies that provided a definition with the studies that only provided questions that referenced behaviour-based lists of experiences (e.g., sharing embarrassing pictures, being called names by others, rumours spread by others) and found that behaviour-based lists of experiences yielded a higher prevalence rate than a definition-based measure. Furthermore, Solberg and Olweus (2003) also noted that questionnaire respondents are more likely to subjectively interpret what is meant by bullying if there is not a clear definition, subsequently affecting the prevalence rates. These concerns outlined above create significant problems with comparing the prevalence rates estimated from each study and raise a number of questions about whether a definition should be provided at all.

In order to further examine the effect of the presence of a definition of cyberbullying and the use of the word 'bully', contained in questionnaires, on prevalence rates, Ybarra, Boyd, Korchmaros and Oppenheim (2012) compared the responses of 1200 participants (6-17 year-old) randomly allocated to one of four different forms of a survey question on cyberbullying victimisation: the definition plus word 'bully' form, the definition-only form, the 'bully'-only form or neither the definition nor the word form. The bullying definition included referred to behaviours that are repeated, involve a power imbalance between perpetrator and victim and occur over time (more than once a day). Despite noting that the definition used followed on from the Olweus (1996) definition, no reference was made to intent to harm, instead creating a criterion of over time.

This new criterion essentially extended the repetition criterion to include experiences that occurred over more than just one day. This again creates another example of the specifics of a definition affecting the outcome of results. Despite this, results indicated that including the word 'bully' in the introduction text of a cyberbullying measurement tool resulted in prevalence rates that were similar whether or not the cyberbullying definition was provided.

However, questionnaires that did not include the word 'bully' in the introduction also produced similar prevalence rates regardless of whether the definition was included or not. The authors therefore concluded that the word 'bully' should be included in cyberbullying measurement tools, yet the definition may not be as useful for respondents as much as it is for researchers when deciphering whether or not they have experienced cyberbullying. Results also indicated that when provided with a list of specific examples of bullying experiences, not

including either a definition or the word ‘bully’, resulted in the highest prevalence rates of bullying.

Therefore, according to the research, when constructing a cyberbullying measurement tool, one must be aware that behaviour-based lists of experiences yield the highest prevalence rates. This means that one must remain sensitive when interpreting prevalence rates.

However, behaviour-based lists may be considered as a more objective, accurate measure of cyberbullying considering using the term ‘bully’ in measures could potentially lead to underreporting of experiences. Furthermore, the provision of a specific cyberbullying definition in the introduction text of a measurement tool may be less important for the correct classification of experiences as cyberbullying for respondents, and more central to researchers and for theoretical developments.

Single Item Versus Global Questions

Inconsistency in the construction of questionnaire items also creates a problem for the estimation of prevalence rates because, as previously mentioned, specific behavioural item measurements can yield higher prevalence rates, especially when compared to global item assessments (Gradinger, Strohmeier, and Spiel, 2010). For example, Burgess-Proctor, Patchin, and Hinduja (2009) found that 38% of 8-17-year-old females responded affirmatively to the statement “I have been bullied online”, however when asked later in the survey about their experiences with specific cyberbullying behaviours (such as being ignored by others or disrespected by others), a greater number of participants responded affirmatively (45.8% and 42.9% respectively). Such results showed that despite potentially meeting the criteria for being a victim of cyberbullying, many do not consider themselves to be a victim. The authors noted that this discrepancy also highlights a possible difference between cyberbullying and “the less insidious online harassment” (p. 11). Nevertheless, the discrepancy in the prevalence rates between global and specific item questions is noticeable and makes comparisons of prevalence rates across studies difficult.

To investigate this further, Gradinger et al. (2010) examined whether, and to what extent, such measurement methods influenced the prevalence rates of cyberbullying perpetration. The study compared prevalence rates based on one global item (e.g., “How often have you insulted or hurt other students by sending mean text messages, e-mails, videos or photos to them during the last two months?”) with frequencies from three specific behaviour based items representing victimisation and perpetration (e.g., “How often have you insulted or hurt other students by mean text messages during the last two months? How often have you insulted or hurt other students by mean videos or photos during the last two months?”). The study found that in general, when cyberbullying prevalence rates were measured using global items, lower frequencies were found compared to the specific behaviour-based items. For example, 93.7% of the whole sample ($n=1150$) reported never cyberbullying another individual when asked the global item compared to the specific item frequencies of 89.1% never cyber-calling another, 89.3% never cyber-texting another and 92.7% never sending a video/photo to another. Despite not reporting whether the differences were significant or not, the researchers concluded that the study’s participants may have had an “unclear comprehension” (p. 210) of the global construct of cyberbullying as participants may not have thought to include the specific cyberbullying behaviours under the global construct of cyberbullying. This could therefore suggest that for questionnaires to accurately assess prevalence rates, global items should not be used. However, Ybarra (2009) suggested that it may be that prevalence rates increase with specific lists of

cyberbullying behaviours because more opportunities are created for a respondent to say yes. Or there may be a problem of recall versus recognition of the outlined cyberbullying behaviours.

Another limitation of using global items only to represent the construct of cyberbullying is that no information regarding the specific cyberbullying behaviours can be collected as the prevalence questions are worded too broadly. Using broad questions to define multidimensional constructs is a problem for various reasons including unreliability of items and the inability to elicit detail (Griezel, Craven, Yeung, and Finger, 2008). For example, Hinduja and Patchin's (2010) cyberbullying offending and victimisation measures explicitly outlined the behaviours that comprised cyberbullying in the questions, e.g., "took a picture of someone and posted it online without their permission" or "received an upsetting email from someone you didn't know (not spam)" (p. 212). This approach provided the researchers with a greater opportunity to understand the phenomenon of cyberbullying from a behavioural perspective which is vital to inform subsequent interventions or education. Questionnaires or surveys must therefore consider whether or not the specific behaviours that constitute cyberbullying are of importance or whether global prevalence rates will suffice.

PROBLEMS WITH THE RESPONSE OPTIONS IN CYBERBULLYING MEASURES

Valid estimates of prevalence rates of cyberbullying have also been difficult to achieve due to the differing response options offered to participants on cyberbullying measurement tools. In a review and synthesis of cyberbullying research, Tokunaga (2010) found that cyberbullying was often measured with one or two response items with dichotomous choices (yes/no responses). For example, Li (2007) developed a questionnaire that measured both traditional and cyberbullying and provided participants with yes/no responses to the statements "I have been cyber-bullied (e.g., via email, chat room, cell phone)" and "I have cyber-bullied others" (p. 1789). Prevalence rates were simply reported as percentages based on whether the respondent had answered yes or no. Other cyberbullying prevalence rates have been collected in a similar way (Burgess-Proctor et al., 2009; Finkelhor et al., 2000; Lenhart, 2007; Wolak, Mitchell, and Finkelhor, 2007). Such response options confound the measurement of the bullying criterion repetition as yes/no responses cannot differentiate single from repeated online incidents.

Unfortunately, questionnaires that have provided more response options for participants have done so at the cost of the repetition criterion. For example, questionnaires either use frequency estimate response options such as "never, sometimes or often" (Calvete et al., 2010) or "never, once/twice, a few times, many times or almost every day" (Beran and Li, 2005), or reference periods such as "once or twice a year, a few times this year, about once every week, about a few times every week or never" (Ang and Goh, 2010). Topcu and Erdur-Baker (2010)'s Revised Cyberbullying Inventory appears to be the only measurement tool which enables the distinction between single aggressive acts and cyberbullying by providing the following response options: "never, once, twice or three times, more than three times" (p. 662). Using response items that do not clearly reflect the continuum that exists between a single aggressive act and a repetitive act, especially when repetition is referenced in the definition of

cyberbullying provided, creates a problem for the accurate conceptualisation of cyberbullying and the comparison of prevalence rates. Furthermore, actual prevalence rates may be difficult to determine when response options reference a specific number of times victimisation has occurred (Tynes et al., 2010). For example, Li (2007) provided the response options “less than 4 times, 4-10 times and over 10 times” to the statements “I have been cyber-bullied” and “I have cyber-bullied others”. Moreover, cyberbullying questionnaires have yet to distinguish between those incidents perpetrated repetitively by the same individual and incidents that may have multiple perpetrators such as different individuals disseminating photos or defamatory comments.

Grading et al. (2010) noted that the repetition criteria for a cyberbullying definition should be captured accurately in the response items provided in questionnaires. The authors focused on traditional and cyber bullies and classified them as either occasional or frequent bullies based on two cut-off scores representing the frequency of behaviours experienced in the preceding two months (lenient vs. strict). The ‘lenient’ cut-off was ‘one or two times’ and the ‘strict’ cut-off was ‘two or three times in the last two months’; placing the response option firmly in the repetition criterion threshold. As previously mentioned, this study also investigated the effect of global versus specific item measurement methods; investigating the interaction of these methods with ‘lenient’ and ‘strict’ cut-off scores. The study found that the ‘lenient’ cut-off obviously produced a higher rate of traditional and cyberbullies compared to the ‘strict’ cut-off. More specifically, when using a global item and a lenient cut-off score, 18% of respondents reported they were cyberbullies compared to 51% using specific items. When using a strict cut-off score, global items produced a 3% prevalence rate of cyberbullies compared to 13% using the specific item assessments. The authors concluded that the differences in frequencies of cyberbullies highlight the importance of the specific measurements used to gather prevalence rates for either victimisation or perpetration. Furthermore, when using strict cut-off scores for response options, the difference between the estimated frequencies from global versus specific items is more evident.

Cyberbullying measurement tools therefore need to provide response options that are sensitive not only to the repetition criterion, but they must enable the successful comparison of prevalence rates across studies internationally. Furthermore, comparisons between prevalence rates produced by cyberbullying measurement tools need to take into account both the cut-off score and whether or not specific or global items were used.

VARIETY IN THE DURATION OF TIME PERIODS IN CYBERBULLYING MEASURES

Another feature of the measurement of cyberbullying that has varied across published studies is the duration of reference time periods over which participants are asked to recall incidents of cyberbullying (David-Ferdon and Hertz, 2007). Some research has used the preceding 2 months (Kowalski and Limber, 2007; Ortega et al., 2009), the preceding 6 months (Topcu and Erdur-Baker, 2010; Ybarra, Espelage, and Mitchell, 2007; Ybarra et al., 2007), the preceding year (Tynes et al., 2010; Wolak et al., 2007) or no specified time period (Akbulut et al., 2010; Calvete et al., 2010; Li, 2010). These differences make it difficult to compare results between studies. Furthermore, age comparisons become almost impossible as different time

periods mean participants can draw on their reported experiences of cyberbullying from varying age points. For example, studies measuring the cyberbullying experiences of youth that do not specify a time period may in fact be gathering data on experiences that occurred earlier during childhood. The year that the research data was collected is also important when analysing prevalence rates. Often published results can be 3–4 years old. Considering the rapidly changing technology, this also needs to be taken into account during interpretation.

Ybarra (2009) investigated the time periods provided in 14 cyberbullying research papers (study dates ranged from 1999–2008) and found that 5 papers did not specify a time period, five used ‘ever in the past year’, two used ‘ever in the past couple of months’, one used in the ‘current school year’ and one used ‘this semester’. Ybarra found that in the sample of research papers selected for comparison, time period did not appear to have a significant effect on prevalence rates. However, Ybarra concluded that this may be the case due to the considerable variability in reported prevalence rates across the studies included in this chapter (6–72%). Either way, time periods for response options on cyberbullying measurement tools need to be taken into consideration when comparing prevalence rates and other outcome measures across studies.

INCONSISTENT REPORTING OF VALIDITY AND RELIABILITY OF CYBERBULLYING MEASURES

Throughout the research on cyberbullying, reporting psychometric data on measures of cyberbullying and its related constructs remains inconsistent. This could be said to have occurred due to the exploratory nature of many surveys and questionnaires developed specifically for each research article. For example, Li (2007) did not provide any psychometric data for his cyberbullying survey, but reported the frequency of responses. Tokunaga (2010) speculated on the future of cyberbullying research and surmised that the development of valid and reliable measurement tools to “improve the overall quality of research by allowing scholars from divergent perspectives the opportunity to measure constructs equitably” (p. 283) is a priority. Some researchers have attempted to address the psychometric data inconsistency by developing their own measure of cyberbullying.

Topcu and Erdur-Baker developed the Cyber Bullying Inventory after a series of face-to-face interviews and focus groups with teachers and students in Turkey. A revised version was then published in 2010 after a review of the recent literature and a further focus group of students aged 16–18 years who were recruited from Turkish schools. In the revision, both cyberbullying perpetration and cyberbullying victimisation loaded onto a single factor. Internal consistency of the victimisation and perpetration scales were $\alpha = .82$ and $.75$, respectively. Convergent validity of the inventory was conducted using the Traditional Bullying Questionnaire developed by Topcu (2008). The relationship between the questionnaires was positive and statistically significant indicating that there was a considerable overlap between those who engaged in traditional bullying and cyberbullying perpetration and those who were victims of traditional bullying and cyberbullying. The validity of this inventory across cultures has yet to be determined.

Tynes et al. (2010) developed the Online Victimization Scale (OVS) consisting of four subscales representing the construct of online victimisation using online re-embodiment theory as a theoretical foundation.

The scales were general victimisation, sexual victimisation, individual racial discrimination and vicarious racial discrimination. Two confirmatory analyses were conducted on 14-19 year old participants and both sets of analyses supported the hypothesised four-factor model for online victimisation.

To validate the OVS, several measures that have been found to be associated with traditional victimisation were used including the Profile of Mood States-Adolescents (Terry, Lane, Lane and Keohane, 1999), the Rosenberg Self-Esteem Scale (Rosenberg, 1965), the Perceived Stress Scale (Cohen, Kamarck and Mermelstein, 1983) and the Satisfaction with Life Scale (Diner, Emmons, Larsen and Griffin, 1985). The OVS was associated with all inventories.

Another approach to providing psychometric data for cyberbullying questionnaires rather than developing a new measure of cyberbullying, is to extend a previously validated measure of traditional bullying. Griezel et al. (2008) extended the Adolescent Peer Relations Instrument – Bully and Target, to include an additional 13 items on each scale (bully and target) which measured two forms of cyberbullying (visual and text). Reliability for the higher-order cyberbullying factor was $\alpha = .88$.

Confirmatory factor analysis confirmed the five factor first-order (physical, verbal, social, visual and text) and two higher-order factor structure (traditional bullying and cyberbullying) of the new measure. The researchers based the new items on the original instrument and reported Cronbach's alpha estimates in a sample of year 7-11

Australian secondary school students for both the visual and text subscales as $\alpha = .84$ and $.8$, respectively. Despite the factor structure and internal consistency, the researchers sampled participants from only one school which may limit the generalisability of the results to all school students. One way to allow for potential generalisation of results may be to sample from a population known to utilise the particular technologies measured throughout the instrument.

Although there have been some researchers who have reported measurement psychometrics appropriately, there needs to be a greater shift towards more consistent reporting. This will encourage the repeated use of available measurement tools which will support cross-study comparisons and reduce the number of measurement tools developed solely for the collection of data in a singular study.

The Impact of Culture on the Measurement of Cyberbullying

When measuring cyberbullying, one must consider the impact of culture on its conceptualisation and experience. Multiple studies have outlined the various terms used in multiple countries across the globe to describe not only traditional bullying (e.g., Arora, 1996) but also cyberbullying (e.g., Nocentini et al., 2010). Nocentini et al. (2010) investigated the terms used by adolescents to describe cyberbullying behaviours, and whether these terms were the same across countries. Results indicated that there is not always a direct translation of the term 'bullying', and therefore 'cyberbullying', in other languages. For example, the term 'cybermobbing' was used in Germany, harassment or harassment via the internet or mobile phone in Spain, and virtual- or cyberbullying in Italy.

Menesini et al. (2012) went on to explore whether culture had an impact on the conceptualisation, or definitional criteria, of cyberbullying. Italian, Spanish, Swedish, German, Estonian and French 11-17 year-old participants were randomly allocated a series of scenarios combining the presence or absence of cyberbullying definitional criteria. Results indicated that French participants were more likely to indicate that a scenario was an example of cyberbullying. Support for the criterion of imbalance of power was generally accepted across cultures, whereas intentionality was slightly less accepted in Italy and Germany compared to the other countries' respondents. The researchers attempted to contextualise the high frequencies of cyberbullying responses by the French participants by explaining that in the same year that the data had been collected, a large campaign on school and cyber-violence took place in schools, potentially increasing their awareness of what constitutes cyberbullying.

This research indicated that culture can have an impact on the conceptualisation and experience of cyberbullying. However, there remains a strong need for further research in this area. Therefore, cultural and language differences need to be considered when developing a cyberbullying measurement tool and when interpreting the results from such a measurement tool. This is especially important when the impact of an event, such as the cyber-violence campaign in France, can influence the reporting of cyberbullying.

CONCLUSION

Moving Forward in the Measurement of Cyberbullying

The limitations of the measurement of cyberbullying victimisation and perpetration mentioned throughout this chapter are numerous. However, there has been a lot of progress in what is a new and exciting field of research. There are some simple considerations that if adopted, could aid future research progress in this area of growing significance. Put simply, researchers need to be transparent in the decisions they make when developing a cyberbullying measurement tool. Below are a series of specific points to take into account during such a process.

1. Consider the definition of cyberbullying to be used in the respective research and explicitly state the definition used and how or if each definitional criterion will be measured.
2. Choose a clear purpose for the measurement tool. Consider what variables are to be measured. Are prevalence rates important or the detailed measurement of other variables? Consider the length of the questionnaire/survey and the subsequent effect on the respondents' responses.
3. Choose what environments to measure. Considerations need to be made regarding whether the measure will focus on one CMC or mobile technology environment or behaviours across all environments.
4. Choose what behaviours to measure. Considerations need to be made regarding whether the measure will include all cyberbullying behaviours or a selection of behaviours (e.g., uploading pictures or exclusion).

5. Definition – add in introduction text or not? Consider the purpose of the presence or absence of a cyberbullying definition in the measure. More specifically, consider what definition will be used (see point 1) and which definitional criteria are included in that definition and how this may affect the responses from respondents.
6. Consider whether or not to use single or global item questions. When collecting data, the format of the questions asked needs to be carefully considered based on the required outcome(s). Single item questions produce different data and results compared to global item questions.
7. Consider the type of response options provided for respondents. For the measure to be sensitive to the repetition criterion and enable cross-study comparisons, careful consideration needs to be taken when constructing measurement response options.
8. Time frame provided – will the time frame provided over which respondents are asked to recall incidents of cyberbullying affect the overall prevalence rates? The time frame provided needs to be explicitly stated so that cross-study comparisons can take place.
9. Reliability and validity psychometrics need to be reported. The following are examples of psychometrics that should be considered, depending on the measurement tool, when piloting and validating cyberbullying measurement tools: internal consistency reliability, test-retest reliability, content validity, criterion-related validity, convergent validity, and/or discriminant validity.
10. Consider the culture of the population being measured and whether the culture will affect the interpretation of results or the construction of the measurement tool.

Chapter 69

CHANGING THE STUDENT EXPERIENCE OF CYBERBULLYING THROUGH A CYBER-SAFETY PROGRAM

Ria Hanewald*

Deakin University, Australia

ABSTRACT

This chapter describes the implementation of a cyber-safety program to improve conditions of online environments and behaviour in primary aged school students. It is based on a 2012 research study that examined the effectiveness of internet safety education on the knowledge and behaviour of 72 students in Grade 5 (aged 11 years), especially in respect to Cyberbullying . Data was collected in an independent school in Melbourne, Australia and consisted of a survey of the all male students before and after participating in a program about cyber-safety as well as focus group interviews using open ended questions.

The aims of the pre-treatment survey, cyber-safety intervention program and post-treatment surveys were twofold: firstly, to establish the students' understanding of issues and actual behaviour related to cyber-safety and/or Cyberbullying as a baseline and secondly, to measure the impact that the education program had on their knowledge and attitudes by comparing data gathered from the pre-and post-treatment surveys. Additional information and in-depth insights were gained from semi-structured interviews held in small groups of four to six students. It was hoped that the experience of participating in the cyber-safety program would improve students' knowledge about responsible involvement in digital environments, with a specific focus on decreasing Cyberbullying behaviour.

Results indicate that the difference in the test results is statistically significant. It is therefore concluded that a school wide educational approach to cyber safety and a school culture that reinforces beneficial and safe online experiences will create an environment that discourages Cyberbullying .

INTRODUCTION

The affordability of computers and advancements in mobile technologies has increased internet access. Information and Communication Technology (ICT) are becoming essential for work, education, entertainment and commercial purposes. Today's young people will need to be prepared for this technology rich world, the ubiquitous nature of mobile and digital activities and their inherent risk. One of these dangers is Cyberbullying which has emerged in the late 1990's and has been rapidly growing ever since. It is impacting students' learning and well-being by causing poor academic performance, school drop-out, physical violence, substance abuse, depression and suicide. Mostly affected are students in the middle years of their schooling who are especially vulnerable as they are approaching or going through puberty. While they are dealing with hormonal changes and their developing sexuality they have to simultaneously cope with upheaval of transitioning from primary to secondary schools and settling into a new environment, friendship groups and scholastic expectations. Cyberbullying and its negative consequences creates significant concern for the school, leadership and teachers who are endeavouring to provide the most beneficial environment for their students. Zero tolerance policies for bullying, acceptable use policies for internet access and educational programs to enhance cyber safety are some of these mitigating approaches. This research study investigates the impact of one such prevention program and is placed in the context just described.

YOUNG PEOPLE'S INTERNET ACCESS AND USE

Evidence from the Australian Bureau of Statistics (ABS) in 2011 suggests that nine in ten Australian households (91%) with children have access to a home computer. Over 86 % of children accessed the internet from school and 45 % from other locations such as public libraries or internet cafes. An estimated 2.2 million Australian children (79%) aged between 5 and 11 years reported accessing the internet with usage rates similar for boys and girls. In terms of age, 60 % of 5 to 8 year old used the Internet which increased to 96 % by the time these children were between 12 and 14 years of age (ABS, 2011a).

The Australian Communications and Media Authority (ACMA) found that every Australian family has at least one mobile phone and most posses three mobile phones. In terms of Internet use, 96 % of children aged between 12 and 14 years spend an average of 49 minutes per day online (ACMA, 2008).

While the most popular use for the internet was for educational activities for the majority of children (85%), playing online games came second (69%) followed by one in five children (22 %) who visited or used social media sites (ABS, 2011a).

This equates to around 18 minutes spent on messaging, 15 minutes spent in online games, 11 minutes in social networking sites and five minutes on emails (ACMA, 2008).

Australia, New Zealand, Canada and the United Kingdom all had relatively similar levels of household internet access ranging from 72 % to 77 % (ABS, 2011b). In the United States 93 % young people aged between 12 and 17 years have access to the internet (Cowie and Colliety, 2010).

Internet access was at 72 % for all households in 2010 as the Organisation for Economic Co-operation and Development (OECD) established in their examination of 34 countries.

Young people in the European Union spend 88 minutes per day online. The majority of these 13 to 16 year olds watched YouTube (86%), communicated online (75 %) through email, Instant messenger or on social networking sites. Almost a quarter (23 %) visited chatrooms, virtual worlds, blogged and shared files (Livingstone, Haddon, Görzig and Ólafsson, 2010). A study of 347 girls (aged 11 to 19 years) in New Zealand revealed that more than a third (33.5%) did get in touch with a stranger whom they had meet online and (34.5%) did not tell their parents about it. More than half (60 %) had given out their details (name, address, phone number) or pictures. Three quarters of the girls (75%) said that they were only occasionally controlled by their parents and more than a third (37.5%) were never monitored (ISG, 2001).

Although the study in this chapter is conducted in Australia, the above data indicates that the penetration of internet access, the amount spent online and the spread of activities is similar in the rest of the developed world.

CHALLENGES AND OPPORTUNITIES OF TECHNOLOGY

Without doubt, online environments can offer enormous benefits for learning and self-exploration, opportunities to communicate with others and gain social support, enjoy cross-cultural interactions and explore one's identity. However, as young people increasing spent more time online, the risks, especially for involvement in Cyberbullying is increasing too (Mishna, Khoury-Kassabri, Gadalla and Daciuk, 2011).

Empirical studies over the last decade in Australia, Canada, the UK and the USA have indicated that unsafe online behaviour and specifically Cyberbullying among young people has increased significantly. This creates numerous concerns in terms of the emotional, social, academic and legal harm that such incidents may have on a young person's life, which in turn has developed into a major worry for governments, educational authorities, child protection agencies, parents, teachers and young people (Hanewald, 2010).

Cyberbullying peaks during early adolescence. This is a time when young people have access to the internet and mobile devices (i.e., phones, tablets), feel comfortable with technology and believe that they are anonymous while online. Cyberbullying increases during primary school as students become more proficient with technology, reaches its highest levels in middle school during a time of personal change (i.e., onset of puberty, developing sexuality) and social tension (i.e., transition to secondary school, new friendship groups) until it decreases in high school as young people gain their driving license and use that mobility, which takes them away from the computer (Li, 2006; Beale and Hall, 2007; Williams and Guerra, 2007; Snakenborg, Van Acker and Gable, 2011; Hanewald, 2012).

The steady rise of Cyberbullying might be explained by young people's misconception that they are invisible online and cannot be identified if they give themselves false or fictional names for profile on social networking sites (i.e., Sunflower, Mickey Mouse) or for their email address (i.e., Hotgirl123@hotmail.com; bestman2012@yahoo.com). This assumed anonymity frees young people to say and do anything online as they believe that there are no consequences for their unacceptable behaviour (Beale and Hall, 2007). Hiding behind a computer screen seems

to provide a protection that affords displays of aggressiveness which young people may not dare in the 'real' world.

The impact of Cyberbullying includes emotional adjustment problems, difficulties with relationship and fitting into the school environment (Campbell, 2005). Victims of Cyberbullying suffered devastating psychological effects such as high level of fear, rage, powerlessness and depression which led to a state of anxiety, loss of confidence and withdrawal from school and friends (Hoff and Mitchell, 2009). The emotional distress of being cyber bullied is often accompanied by an inability to concentrate which causes poor academic failure (Mishna, Cook, Saini, Wu and MacFadden, 2011).

The victim's torment is further exasperated by a world-wide who is witnessing the public humiliation, the permanent digital record of the embarrassment, which can be endlessly duplicated and shared online as well as the intrusion into the victim's home as Cyberbullying penetrates even a person's most private spaces. Given the proliferation of internet access and usage by young people and the potential damage, it has become a priority to ensure that efforts are made to prevent inappropriate online behaviour. There are a range of methods to protect children and young people from the dangers of the internet, which can be categorised into three large approaches: electronically, legally and educationally (Hanewald, 2008).

APPROACHES TO INTERNET SAFETY

The three major approaches to address online safety are electronically, legally and educationally and will be discussed in more detail below.

The electronic approach uses technological solution such as blocking and filtering software (e.g., Net Nanny, CYBERSitter, Cyberpatrol, McAfee, Norton, Cyber Sentinel) that prevents access to internet content that is obscene, harmful or inappropriate and blocks the posting of such materials. It not only limits young people's exposure to inappropriate online materials, it also prevents them from accessing websites that are not approved, blocks the posting of personal information online, prevents unwanted contact and may even force the closure of the browser. Additional functions include setting time limitations for online use and the tracking of online activities through the capturing of screen pictures. Schools, libraries, some internet cafes and parents in their homes have installed these software programs to ensure safe and beneficial online experience for young people. However, while blocking, filtering and parental control software can be installed on laptops and computers it cannot be used on mobile or smart phones. Although Apple has introduced restriction options on their iPad, iPhone and iPod touch, it only applies to parental control that restricts access (e.g., to Safari, YouTube, iTunes, Ping, Multiplayer Games, Adding friends in Game Center) and disables purchases of Apps. The potential for bullying through text messages or 'sexting', the sending and receiving of sexually explicit images is still given.

Technological solution such as internet blocking and filtering software may lull educators and parents into a false sense of security, assuming that children are protected from any harm. This might cause adults to cease or relax their direct supervision of any children who are using a computer or mobile device. For example, in the EU 49 % of young people have a computer in their bedroom and go online there which allows for a great deal of privacy (Livingstone, Ólafsson, and Staksrud, 2011). A computer in the family home's living room is easier for

parents to supervise than one in a child's bedroom. Likewise, computers in the school library or in a computer lab are easier to supervise by teaching staff than students' individual laptops, tablets, mobile or smart phones as these can be carried to secluded or restricted areas such as the students' washrooms. Photos taken by students in the toilets or the shower area after physical education class can be easily used for sexting or Cyberbullying if victims are unaware that they are being caught on camera in a nude or semi-nude state.

Another drawback of technological solutions is the fact that internet firewall or blocks are not as impenetrable as parents and educators may think. These software programs can be circumvented with relative ease as sixteen-year old Tom Wood from Melbourne showed. The school boy needed only 30 minutes to hack through the Australian Government's new \$ 84 million Internet porn filter (Hanewald, 2012).

The legal approach includes the use of existing as well as the introduction of new legislation to deter potential perpetrators and punished offenders. For example, in the Australian state of Queensland, a teenager was charged with possession of child exploitation materials because he had the topless photo of his 15-year old girlfriend on his phone (Hearn, 2010). The prospect of a permanent criminal record for child pornography offences might be accompanied by a prison sentence and a life time of limited career and professional prospects. Many employment sectors (education, finance, law enforcement) require a criminal records check. A prior conviction as a sex offender will automatically exclude applicants from any appointments for positions.

Pleading ignorance due to their youth and inexperience is not a sufficient excuse as 19-year old Christopher Cross from South Australia discovered. He was charged with criminal defamation after setting up a Facebook group that targeted a local police officer. Although he "...didn't realise you could get in trouble for things on the internet" he was convicted (Hunt, 2009).

The perhaps most well known incident of new legislation occurred in the USA where the "Megan Meier Cyberbullying Prevention Act" was introduced on 22 May 2008. It was in response to the suicide of 13-year old school girl Megan Meier who hanged herself after being cyber bullied through MySpace and MSN Messenger. She thought to be in an online relationship with a boy called Josh Evans. However, this was fictitious person with an invented personal profile on MySpace by the mother of one of Megan's friends. This adult pretended to be Megan's boyfriend and taunted her with nasty messages until she killed herself. Although convicted, the adult was later acquitted (Huffstutter, 2007).

Legal approaches are also limited by the jurisdiction of the respective state or nation state, whereas Cyberbullying knows no geographical boundaries and is not limited to countries and their borders.

The educational approach is usually through internet safety programs. A plethora of internet safety educational materials have appeared rapidly such as websites that educate children and parents about the dangers of the internet. There are a number of formal and informal internet safety programs in existence. Non-profit and government agencies have been delivering internet safety programs to children and parents in their communities. These attempts from state education departments, government agencies, public libraries, charitable organisations and enthusiastic individuals produced a glut of materials including websites, cyber safety days, stickers, phone help lines, posters, brochures, flyers, invited guest speakers to give presentations or conduct workshops, displaying posters, class or individual discussion

with students on cyber safety, online interactive activities, video clips with vignettes about internet safety and so on.

Schools, administrators and educators are faced with the task of keeping students safe while at school and in particular while using digital environments at school. Therefore, most schools have now included internet safety messages into their curriculum and developed internet guidelines, netiquette rules and Acceptable Use Policies (AUP). Students and often also their parents have to sign formal agreements to adhere to these school policies. Any violations of these school regulations will be punished with a loss of internet privileges, suspension or even expulsion from school. Some schools focus on their role of equipping students with a moral compass with which they will be able to navigate cyberspace safely and responsibly and therefore concentrate their efforts on developing digital citizenship in their students.

It is anticipated that the range of these activities and funding to develop and disseminate internet safety education will increase even more in the next decades to address concerns of problematic online experiences by young people. Already, a considerable number of educational and technological initiatives have been launched although the effectiveness of such endeavours is largely unproven.

Some researchers have even highlighted the lack of impact of cyber safety programs as it does not reduce young people's risky online behaviour (Campbell, 2005). For example, a Canadian study by Crombie and Trinneer (2003) measured the effectiveness of an interactive computer game for students in Grade 6 and 7, which was designed to help students develop better attitudes towards online safety and assist them in developing their own internet safety rules. Their findings indicated that the students did increase their knowledge about internet safety but the students' actual behaviour did not change significantly. Just knowing about internet safety is not enough the knowledge needs to be applied.

A Belgian study concentrated on the primary students' (Grade 4 to Grade 6) perceptions and behaviours to using the internet. Findings of 1700 children and their headmasters indicated that there were high levels of unsafe internet use at home. School-based interventions were less effective than parental control in impacting on the behaviour of children. Their results pointed at the need to give schools directions for adopting safe internet measures (Valcke, Schellens, Keer, and Gerarts, 2006).

A British study concentrated on the students' behaviour in chatrooms and whether they applied the internet safety guidelines in that environment. Findings of 1369 children aged 9 to 16 years of age indicated that they were aware of the safety guidelines for online environments but did not know how and when to apply these (O'Connell, Price and Barrow, 2004). Hence, when implementing an anti cyber-bullying program a number of factors should be considered according to Couvillon and Ilieva (2011) such as developing young people's judgement about responsible and safe conduct online, practicing and promoting appropriate behaviour while simultaneously mirroring the nature of access and connectivity. Cyber safety programs should be a sustained strategy rather than a one-off event and imbedded within a school-wide proactive approach. This includes a commitment to keeping abreast of new devices and features and other technological developments. Teachers' attitude should be underpinned by an acknowledgment that anyone can be cyber-bullied and that the effects can be highly destructive. With this in mind, the research in this chapter attempted to evaluate one such cyber safety programs, measure the impact that it has on students' behaviour and attitude and thus gains insights on its effectiveness.

RESEARCH DESIGN

The study was conducted during the first half of 2012 at an independent school for boys only in Melbourne, Australia. Most students live in the catchment area, which is characterized by middle to upper class families. The students have usually attended the local primary school within close proximity with only very few boys travelling from further away. The campus holds 605 students, with approx. 125 students enrolled in 5 classes across year level 5. The students in these classes are typically 10 to 11 years old boys. According to school demographic data, 85 % of the students in Years 5 and 6 have their own mobile phone. The school espouses a Christian ethos and has a reputation for constantly striving to improve hence already strong policies against traditional bullying are in place. The low level of physical bullying is evident in only a few incident reports per year. A restorative practice approach is part of the existing school culture.

For this study, students in Year 5 were selected as they were all new to the school and the cyber safety awareness and prevention program aims to provide a foundation for their start in this new environment. While none of the students had prior experience with the school's cyber safety awareness and prevention program, they may have participated in cyber safety activities at their previous school. Alternatively or additionally, they may have received some guidance from their parents, siblings or friends or they may even have informed themselves through the media about strategies for safe online behaviour. Hence, it was anticipated that the pre-and post-treatment reflected changes in online attitudes and behaviours directly related to the school's cyber safety awareness and prevention program. The main aim of the educational cyber safety awareness and prevention program was to develop the students' understanding of Cyberbullying and give them a range of strategies to stay safe online.

The pre-treatment survey was administered at the beginning of the 2012 school year, which is Term 1 (February to March). The cyber-safety intervention program and post-treatment took place in Term 2 (April to June) of 2012. Semi-structured interviews with small focus groups of students were held after the training program, which added qualitative data to the quantitative data sets. The 15 question of the survey were administered online (through Zoomerang Online Surveys and Polls) and taken from the High-Wire Act, Cyber Safety and the Young Interim (Joint Select Committee on Cyber Safety, 2011).

The latter decision was based on the fact that the validity and reliability of this instrument had already been established and was therefore deemed appropriate and suitable. The focus of the survey was on young people's opinions and experiences about cyber safety and their techniques to diminish online risks, specifically their rate of cyber safety awareness, the kinds of information that they share and their support networks in case of a Cyberbullying incident.

RESEARCH AIMS

For some years now, the school had implemented an age-appropriate cyber safety awareness program for all students in the middle years with the aim that they would learn about and understand the dangers of the Internet and strive to be safe online. The overall object of the cyber safety awareness program was to increase students' capacity to employ a number of strategies to protect their identity and privacy while at the same time discouraging potential

attitudes and behaviours that might lead to or have been causing Cyberbullying .However, the effectiveness of this program has not been evaluated, which means it is unclear if and how much and what kind of impact the cyber safety program has on the students' knowledge and behaviour.

The research is aiming to ascertain this factor, that is evaluate effectiveness of the internet safety program, determine any modification to increase its success and implement any needed adjustments. Hence, the fundamental research question tried to explore in what way the cyber safety program changed the students' behaviour, knowledge and attitude. It was hoped that it would contribute to a knowledge base on what works in internet safety education by establishing what information students remember from a cyber safety education programs and how they apply this knowledge into their daily online conduct.

DATA COLLECTION

At the start of the 2012 academic year, a total of 128 students were enrolled in the Year 5 cohort. Written permission for participation in the research was given by 72 families (56.2%), with 28 (21.8 %) of families actively withholding consent, a further 26 families (20.3 %) simply failed (forgot) to respond. Two written consent forms (1.5%) were filled out incorrectly, which made them invalid. The mixed method data collection consisted of a pre-and post survey, which was administered online had 15 questions and took about 10 minutes to complete. The qualitative part comprised of focus groups interviews of five to 7 questions with randomly selected students from the cohort. The sessions were held either before school or during morning recess and lunch periods and the limited time available meant that each focus group's involvement did not exceed the set 15 minutes.

The pre-treatment survey established a baseline about their knowledge and behaviour whereas the post-treatment survey indicated the impact of the cyber safety program. The actual prevention program was Cyber Quoll provided by the Australian Communication and Media Authority (ACMA) which had been developed specifically for upper primary students (Year 5 and 6). It comprises six computer-based activities to educate students about appropriate behaviour and personal online and e-security issues (e.g., avoiding viruses, recognizing predators) while equipping them with a number of strategies to make safe choices while navigating cyberspace.

The program had already been used at the school in other year levels with anecdotal reports of success by teachers. The current study aimed to provide some empirical evidence to either support or refute those claims. In addition to the quantitative data gathered through the pre-and post treatment surveys, qualitative data was collected to gain greater and more in-depth understanding.

DISCUSSION

The online survey administered prior to the intervention provides baseline data on the students' general knowledge, behaviour and attitudes in regard to online activities.

CYBERBULLYING PREVALENCE AND RESPONSE

A total of 67 students completed the survey. In terms of actually Cyberbullying during the last year, only seven students (10%) reported being cyber bullied and only 16 students (24%) had heard of somebody else who had been cyber-bullied. These findings are below those commonly found in the literature (Hanewald, 2008, 2010, 2012). Students were asked pre-treatment “When you were cyber-bullied, what did you do about it?” The majority (19) told an adult or family friend. Others (17) blocked the bully or removed the person as friend, stayed offline (10), told a friend (5), got back at them (4) or spoke to the bully (1). Only one student did nothing and six indicated ‘other’. The high response rate of 62 students’ reaction to being cyber bullied compared to only six students who actually indicated that they had been cyber bullied seems to be caused by a misread of the question with student reading ‘if’ rather than ‘when’.

STUDENTS’ KNOWLEDGE SOURCES ABOUT ONLINE SAFETY

When asked “where did you learn about safety when using the internet?” most students nominated school (pre-treatment = 55, post-treatment = 63), information found online (pre-treatment = 3, post-treatment = 11), family (pre-treatment = 42, post-treatment = 29), and friends (pre-treatment = 6, post-treatment = 6). Two students indicated that they had not learned about online safety before the treatment. This is perhaps the clearest endorsement of cyber safety programs in schools as it is the source of knowledge regarding online safety for the majority of students while family as information source came as a close second.

PERCEPTION OF ONLINE SAFETY

When asked “Have you ever felt unsafe online?” for both the pre-and post treatment survey, the majority (69%) replied that they felt safe online and only a third (31 %) had felt unsafe online both in the pre-and post treatment survey. When asked “Are you worried about your safety when you are on the internet?” there was a slight increase in concern from the pre-treatment “yes” reply of 41 students to the post-treatment “yes” reply of 51 students which might be due to greater awareness of the potential dangers of online engagement. In exploring the issue of anonymity 29 of participants (43 %) indicated that they thought to be anonymous when online while 38 students (57 %) knew that they were identifiable.

Post-treatment, the figures changed to 34 % (anonymous) and 66 % (not anonymous) respectively, showing greater awareness of the traceability of their digital footprints.

AWARENESS OF PRIVACY

Students’ awareness in regard to the privacy of some details was very high both before and after the cyber safety program. For example, there was unanimous agreement that it was not okay to give out their family’s bank details over the internet. Prior to the cyber safety program,

only one student was unsure if giving out his password for his email address was okay which changed to 'no' afterwards. For the disclosure of their physical address, four students were unsure before the prevention program but changed their minds in the post-survey and would not give it out. In terms of 'sexting', only one student would send nude or semi-nude photos to others via phone or email while another student was not sure. After the cyber safety program both students thought it was not okay to do so. When it came to posting regular photos of others online without their permission, the majority (96%) thought it was not okay before treatment, which increased to 100 % in the post treatment survey.

DISCLOSURE OF PERSONAL INFORMATION

However, there was more uncertainty in regard to the disclosure of other personal information: 17 students (25 %) were happy to put their name on the internet, eight were not sure and 42 students (63%) would not do. After the cyber safety program, the eight uncertain students decided mostly against it, thus tallying as 47 students (70%) unwilling to put their name online in the post-treatment survey. Online disclosure of students' date of birth yielded comparable findings: prior to the cyber safety program, the majority (69%) thought it to be unsafe, 15 students (22 %) thought it be acceptable while six students (9%) were not sure. In the post-treatment survey, 87 % thought it to be unsafe, only one student was unsure while eight students (12 %) still thought it was okay. Eleven students (16 %) thought it was okay to put their school's name online in the pre-treatment survey, while eight were being unsure. In the post-test there was still one student who thought it was okay to do so. One student was happy to give out his mobile phone name before and after the treatment, while three boys were unsure which changed to two boys only after treatment. While the disclosure of single items might not be a major security concern, the aggregation and cross-referencing of several items allows predators to identify and track their potential victims, which might have to be stressed to convince all students.

DISCUSSING AND DISCLOSING ONLINE SECURITY ISSUES

Students were asked if anyone in their family talked about how to stay safe when online with 66 % responding positively while 34 % were negating the question in the pre-treatment survey. Unexpectedly, this reduced to 58% and 42 % respectively. Given the articulation and permission seeking process of this study and the accompanying cyber safety program, greater discussion in the home's of the students would have been assumed. It could be speculated that a reduction in family discussions might be due to the cyber safety program as parents might reason that this issue is being taken care of in school and needs no further attention.

When asked "If you were worried about something you saw online, who could you talk to?" most students nominated their family (pre-treatment = 65, post-treatment = 63), their friends (pre-treatment = 24, post-treatment = 26), their teacher (pre-treatment = 33, post-treatment = 47), the police (pre-treatment = 26, post-treatment = 21), and administrators (pre-treatment = 13, post-treatment = 15).

STUDENTS' REFLECTIONS ON INCREASING SAFETY ONLINE

When asked “What do you think can be done to make you safer online?” most students thought that learning at school (pre-treatment = 44, post-treatment = 47) and discussing it more with family (pre-treatment = 44, post-treatment = 36) would help. A smaller number thought that internet filters would help (pre-treatment = 13, post-treatment = 21) and increased policies and their enforcement (pre-treatment = 9, post-treatment = 13). One student (pre-treatment) thought that nothing needs to be done as it is safe online, which changed to five students after treatment. When asked “What could be done about Cyberbullying ?” the majority of students suggested more policing (pre-treatment = 36, post-treatment = 42), an increase in Internet filtering (pre-treatment = 39, post-treatment = 24), the provision of safe youth centres with entertainment and recreational centres (pre-treatment = 26, post-treatment = 23), and other (pre-treatment = 18, post-treatment = 19).

STUDENTS' REFLECTIONS ON THE MOTIVATION FOR CYBERBULLYING

This multiple choice questions (10 options) allowed several answers. Most students thought that the reasons “Why do people cyber bully?” were a bad home life (pre-treatment = 34, post-treatment = 38), people looking for a fight (pre-treatment = 29, post-treatment = 32), a lack of respect for others (pre-treatment = 29, post-treatment = 38), and a dislike of people from different backgrounds (pre-treatment = 28, post-treatment = 19). Dislike of people with disabilities (pre-treatment = 19, post-treatment = 15), boredom (pre-treatment = 19, post-treatment = 25), mixing with the wrong crowd (pre-treatment = 19, post-treatment = 24), fighting over girls/ boys (pre-treatment = 13, post-treatment = 21) copy cat of news stories (pre-treatment = 6, post-treatment = 5), and other (pre-treatment = 21, post-treatment = 18) received lesser endorsements.

Overall, the Cyberbullying incidents in this study are lower than those found in the literature which would explain why the majority of students felt safe online. Before the cyber safety program, most students had already gained knowledge about safe online use from school or family members and were very aware of the need to keep personal information private. Hence, very few students were prepared to disclose personal details online, post nude or semi-nude photos of them or upload pictures of others without their prior permission. This further improved after the cyber safety program but only very slightly. Discussion of online security issues in the family home decreased after the cyber safety program, probably reflecting complacency and reasoning that the issue was handled at school. Students' ideas about ways to increase cyber safety and their thoughts on the motivation of cyber bullies changed little between pre-and post treatment.

CONCLUSION

School have a commitment to provide safe and enriching online experience for students. In preparing students for 21st century learning, there also has to be a dedication to create an

educational technology environment that promotes safe and wise internet use. Schools are therefore seeking ways to protect children from internet dangers and equip them with the skills needed to ensure beneficial online experiences. Initiatives might include the installation of internet filters and blocks, prevention and education programs for parents and/ or their children that are delivered either online or offline through face-to-face presentations, video games or interactive software (Mishna, et al. 2011).

Due to the perceived need and the significance of the problem, a plethora of programs are available but their effectiveness is not proven. Hence, this study aimed to explore the effect of a cyber-safety program. It was hoped that it would reduce probable cyber-bullying by educating students about safe and responsible online behaviour while at the same time empowering victims and bystanders of cyber-bullying to report incidents and thus deter cyber bullies.

The findings of this study, namely the online survey pre-and post treatment indicated a slight increase in students' awareness of cyber safety and slightly more caution in disclosing personal information. Most students were already practicing safe online behaviour, which seems due to knowledge gained at school and in the family home.

However, the study described in this chapter is limited by the data, which comprised only surveys and focus group interviews but not actual observations of students using the Internet. Apart from the students themselves, parents and teachers could have been involved in questionnaires, phone interviews or focus groups to corroborate a more comprehensive picture of the situation. Furthermore, the study is limited by the application of a particular intervention (Cyber Quoll). Other interventions may yield rather different results.

Another factor is gender, which is a significant element in cyber-bullying according to Li (2006). Boys are much more likely to be cyber-bullies than girls. In self-reports, males disclosed themselves at a much higher rate as bullies than females did (Li, 2006). It is therefore assumed, that a co-educational school or a girls only school would have produced significantly different results than those obtained in this boys only sample.

Nevertheless, the data showed that schools are the major source of information on cyber safety. Hence, cyber safety awareness programs should be an essential part of the curriculum. Although the pre-and post treatment difference in this study was small, the cyber safety training did have a positive effect. While most students in this Grade 5 cohort were highly aware and effective in keeping themselves safe online, the attitude and behaviour of a few students still remains a concern even after the cyber safety training program. Investigating the training resistance of those young people will be a challenge for future research.

Chapter 70

SETTING AN AGENDA FOR FUTURE RESEARCH INTO CYBERBULLYING USING SOCIAL NETWORK ANALYSIS

and Steven Eggermont²***

¹University of Antwerp, Belgium,

²KU Leuven, Belgium

ABSTRACT

Cyberbullying takes place within the context of different human interactions. It is therefore not merely “individual” behavior, but also highly “social” and embedded in the surroundings. The present chapter explores how research on cyberbullying can benefit from studying this behavior as a social and group phenomenon, analyzing interactions and relationships within the relevant contexts. For this purpose, the use of social network analysis (SNA) is proposed, as a highly suited perspective and toolset to study contacts and social ties. It is able to link cyberbullying to young people’s offline, as well as their online interaction networks. This approach has proven valuable to study social processes in traditional bullying, such as status acquirement, social influence and norm adherence. Ultimately, the chapter aims to set a research agenda to further the understanding of cyberbullying in adolescents’ social contexts using a unique methodological perspective.

INTRODUCTION

According to the often cited definition by Smith, Mahdavi, Carvalho, Fisher, Russell and Tippet (2008), cyberbullying is "an aggressive, intentional act carried out by a group or individual, using electronic forms of contact, repeatedly and over time against a victim who

* Corresponding Author’s Email: denis.wegge@ua.ac.be.

cannot easily defend him or herself" (p. 376). Research shows that cyberbullying is a common phenomenon, especially amongst (early) adolescents.

As indicated in the definition of Smith et al. (2008), cyberbullying takes place within a relationship between two or more people. Currently, however, not much information is available about the type of relationships in which cyberbullying occurs, and the broader social context these relationships are situated in. This is remarkable, as in research on traditional bullying (and more broadly aggression), the social context has been an important research focus for several decades and has proven to be very useful for understanding this type of behavior (see e.g., Cairns, Cairns, Neckerman, Gest, and Gariépy, 1988; Ennett and Bauman, 1993; Espelage, Green, and Wasserman, 2007; O'Connell, Pepler, and Craig, 1999; Salmivalli, 2010; Salmivalli, Huttunen, and Lagerspetz, 1997). This social context has been explored using several types of research methods, ranging from qualitative methods such as focus groups, in-depth interviews, and (participant) observation (Baldry, 1998; Craig, Pepler, and Atlas, 2000) to quantitative approaches such as (traditional) survey research (Lambert, Scourfield, Smalley, and Jones, 2008) and social network analysis (Dijkstra, Lindenberg, and Veenstra, 2007; Espelage, Holt, and Henkel, 2003). Social network analysis has proven to be a particularly suited method to study the relationships between, on the one hand, individuals' status in a (peer) network, their belonging to "cliques", and the characteristics of the larger social network they are part of (e.g., the "density" of their class unit in school) and, on the other hand, their involvement in traditional bullying.

In this book chapter we will explore how (future) research on cyberbullying might use social network analysis to gain a deeper insight into the social context that shapes and is influenced by cyberbullying. To do this, we give an in-depth overview of how adolescents – who are avid users of Information and Communication Technologies (ICTs) – connect online. Following the two perspectives ("full network analysis" versus "ego network analysis") that can be taken when conducting social network analysis (SNA), we will make an (analytical) distinction between 1) the "online communities" in which youngsters participate based on, for instance, common interests (e.g., hobbies, games...) with people they often do not know offline (in this case the "full network" that is being departed from is the online network itself), 2) the online connections or networks (e.g., e-mail networks, text messaging networks...) that result from adolescents' participation in full offline networks (such as their school environment) and 3) the online ego networks of youngsters (e.g., the total number of people youngsters communicate with online, regardless of the context they know these people from). Based on insights into aspects such as status, group formation and group norms in online contexts, we will set an agenda for future research into cyberbullying using SNA.

1. SOCIAL CONTEXT AND TRADITIONAL BULLYING

Research on traditional bullying has proven that there are a number of reasons why studying the social context in which bullying takes place is important. First, in order to understand bullying, merely focusing on the classical roles of "bully" and "victim" does not suffice. Bullying often occurs in a social situation in which the bullying is witnessed by other group members, who can have an important impact by joining the bully, supporting the victim, ignoring the behavior etc... (O'Connell et al., 1999; Salmivalli, Lagerspetz, Björkqvist,

Österman, and Kaukiainen, 1996). Salmivalli and colleagues (1996) distinguished as much as six possible participant roles in a bullying situation: bully, victim, reinforcer of the bully, assistant of the bully, defender of the victim and outsider.

Considering bullying as a group phenomenon, second, helps us to better understand individuals' motives to bully. It is widely documented in the literature that bullying is often used as a means to acquire or maintain a high social status within a certain peer group: higher status adolescents assert their power by intimidating or ridiculing lower status victims (see e.g., Hawley, 2007; Pellegrini, Long, Solberg, Roseth, Dupuis, Bohn, and Hickey, 2010; Salmivalli et al., 1997). The importance of social status in bullying was observed in ethnographical studies (Adler and Adler, 1995; Eder, 1985) and was confirmed in studies using sociometric and social network analysis (Farmer and Rodkin, 1996; LaFontana and Cillessen, 2002; Prinstein and Cillessen, 2003).

Third, researchers have made a connection between the persistence of bullying behavior and processes of influence or contagion among peers (Mouttapa, Valente, Gallaher, Rohrbach, and Unger, 2004; Olweus, 1993; Salmivalli, 2010; Sijtsema, Ojanen, Veenstra, Lindenberg, Hawley, and Little, 2010). In empirical studies, researchers often found that friends are similar in terms of both attitude towards bullying and involvement in bullying (Cairns et al., 1988; Espelage et al., 2007; Espelage, Holt, and Henkel, 2003; Mouttapa et al., 2004; Salmivalli et al., 1997; Sijtsema, Veenstra, Lindenberg, and Salmivalli, 2009; Witvliet, Olthof, Hoeksma, Goossens, Smits, and Koot, 2010). This phenomenon, that is often referred to as "homophily" can partly be explained by processes of self-selection (youngsters are attracted to others that share the same attitude and behavior), but also by processes of interpersonal influence (friends become more alike in their behavior) (Espelage et al., 2007; Sijtsema et al., 2010; Witvliet et al., 2010).

Fourth, also focusing on small groups or "cliques"¹ in peer groups, and larger groups like classrooms helps to understand bullying behavior. Next to personal influence, research has also provided evidence for the existence of "group norms" surrounding bullying. Significant differences in bullying behaviour, and in acceptance or rejection of bullying behaviour across groups and classrooms could be observed: in classrooms where bullying is normative, adolescents who bully are less likely to be rejected or are even liked by their peers (Chang, 2004; Sentse, Scholte, Salmivalli, and Voeten, 2007; Stormshak, Bierman, Bruschi, Dodge, and Coie, 1999).

Lastly, it needs to be remarked that the peer group can also play an important role in averting bullying and in providing support for the victims of bullying. The most effective anti-bullying interventions generally involve entire peer groups (Pepler, Smith, and Rigby, 2004). Youngsters with a good social support network, moreover, are less often involved in bullying and experience less internalizing or externalizing behaviour problems when bullied (Hodges, Boivin, Vitaro, and Bukowski, 1999). Finally, processes of influence also hold for prosocial behaviour: youngsters can learn positive social behaviour from their friends (Barry and Wentzel, 2006).

¹ "Cliques" are "natural groupings" of (five to eight) peers, of which the members have common interests, and spend a lot of time together (Cotterell, 2007, p. 55)

2. STUDYING THE SOCIAL CONTEXT: SOCIOMETRY AND SOCIAL NETWORK ANALYSIS

To study the social context in which bullying occurs, indices of relationships or social structure can be incorporated in traditional research techniques like survey research and qualitative or ethnographic approaches. There are, however, also techniques that explicitly focus on social structure going from basic “sociometric” nomination methods, to more advanced social network analysis techniques. “sociometry” was developed by Jacob Moreno as early as the 1930s (for a history on social network analysis, see: Freeman, 2004). It is most known for its sociograms, which are visual representations of the social reality representing people by dots and relationships by lines (see figure 1). Thanks to several mathematical, theoretical and computational developments, this method could be further developed into a method that is currently known as “social network analysis” (Freeman, 2004).

The term “social network” refers to a set of individuals (also called “nodes”), and the relationships (or “ties”) between these individuals. The basic idea behind social network analysis is that relationships, and the structures these relationships form, matter (Borgatti, Mehra, Brass, and Labianca, 2009, p. 893). Social network researchers describe prominent patterns in social networks, form theories about what these patterns mean, and try to explain behavior of individuals and groups by looking at these patterns or “social structure” (see e.g., Marin and Wellman, 2011; Wasserman and Faust, 1998, pp. 3-10; Wellman, 1988, pp. 19-61; Wellman and Berkowitz, 1988, pp. 1-18). Social network data can be analyzed in multiple ways. Researchers can for instance focus on the position of a person in a network, on the types of relationships in a network, on clusters or subgroups in a network and on the properties of a network in its entirety (for elaborate overviews see: Hanneman and Riddle, 2005; Monge and Contractor, 2003, p. 56; Wasserman and Faust, 1998, p. 25).

Figure 1. Example of a sociogram: mutual friendship in a classroom.

With regard to bullying, social network data are usually collected in a school context. The entire school, a grade, or a classroom hereby forms the network. Researchers ask the pupils to nominate several other students in their school, grade or class they like (or dislike), or who they are friends with. Based on this information, a friendship network is constructed and multiple measures are calculated (e.g., how central a person is in the network, what cliques are formed...). Next, these data are linked with self-reports on bullying behavior, or, with peer-nominations regarding bullying (i.e., asking specifically which pupils in the network are bullies or victims, or asking who they were bullied by/who they bullied). This type of data collection, in which an entire group or network is studied, is called full network analysis.

Another possibility to collect social network data is to map individuals' personal networks. In this case, an individual is asked questions about his or her personal connections. This type of data collection can provide insight into the broad array of interactions people engage in (with close friends, acquaintances, family, co-workers etc.), face-to-face and through technologies (Garton, Haythornthwaite, and Wellman, 1997). While most network research on bullying has adopted a complete network approach, some aspects of adolescents' lives have been studied in personal networks. Most notably this includes the influence of their peers on delinquency (Haynie, 2001), drug use (Lakon, Ennett, and Norton, 2006), and drinking and smoking (Fujimoto and Valente, 2012). When studying personal networks, respondents' connections in all environments can be taken into account, which offers benefits for the analysis of adolescents' mediated ties (discussed further on in this chapter).

3. ADOLESCENTS' ONLINE SOCIAL ENVIRONMENTS

Cyberbullying, like traditional bullying, is a form of negative interaction taking place within a certain social context. In this section we will focus on the characteristics of the online social contexts youngsters are part of, to gain a better insight into the way these contexts might influence bullying behavior (see *infra*). As is evident from the existent literature, adolescents use ICT to create new (online) contacts and to maintain or deepen existing "offline" contacts (boyd², 2010; Kaare, Brandtzaeg, Heim, and Endestad, 2007; Livingstone and Bober, 2005; Subrahmanyam and Greenfield, 2008). From an SNA perspective, it is therefore useful to look at the characteristics of 1) online created (full) networks or "communities" that develop when people with similar interests meet online (e.g., in gaming groups or discussion fora), 2) online networks that are based on (full) offline networks (e.g., how do pupils from the same school communicate online with each other?, who e-mails with whom?, who is befriended with whom on social network sites?) and 3) the online ego networks of youngsters (e.g., the total number of people youngsters communicate with online, regardless of the context they know these people from).

3.1. Online Communities

As mentioned above, the Internet allows people to organize themselves in online communities. Research has studied different online communities, including those formed

² The first letter of the author's official name is in lower case.

around computer games (Boellstorff, 2008; Szell and Thurner, 2012), bulletin boards (Suzuki and Calzo, 2004), chatrooms (Clark, 1998; Subrahmanyam, Greenfield, and Tynes, 2004), fan websites (Baym, 1997; Theberge, 2006) and weblogs (Farid, 2010). One way of looking at the communities is to study them as bounded social spheres in which different group processes take place, such as friendship formation, status acquirement, and social norms formation. In addition, it can be studied how young people handle participation in multiple (sometimes overlapping) online communities. As friendship, social status and group norms are relevant when studying bullying behavior, these issues will now be elaborated further.

Within online social communities adolescents have the ability to develop social relationships. The foundation for such relationships is trust among the members of these online communities; in using pseudonymous identities and nicknames, members get to know each other and recognize their reputation in the community (Henderson and Gilding, 2004). Specific characteristics of computer mediated communication (reduced cues, asynchronous communication, anonymity, transcendence of geography) also facilitates further self-disclosure (Peter, Valkenburg, and Schouten, 2005). Therefore, adolescents may find online communities ideally suited to develop social relationships, even ones that are very intimate and personal (Henderson and Gilding, 2004; Peter et al., 2005; Wolak, Mitchell, and Finkelhor, 2003). The online environment may thus be seen as an additional setting in which friendship or more casual relationships are constructed, besides the usual connections in more traditional settings, such as family, school and leisure time (see for instance McGinnis, (1997).

As social status proved a key concept in explaining adolescent bullying, the notion is explored in the context of online communities as well. On the one hand, it can be argued that status is less visible in an online environment. As access to the community is easy and offline status symbols and appearances are hidden, online interactions may be characterized by equality of participation (Siegel, Dubrovsky, Kiesler, and McGuire, 1986) and equality of status (Dubrovsky, Kiesler, and Sethna, 1991). On the other hand, while social status may not be immediately apparent in online communities, users do attract certain regard over time. Similar to the offline world, being well connected serves as an indication of status. In online communities, this would comprise belonging to certain subgroups of the community, being affiliated with the right users and being familiar with the community's conventions (Axelsson, 2002). In addition, community members can also gain status by "giving gifts". In a virtual community this means providing other members with information, opinions and advice. Lampel and Bhalla (2007) identified status seeking as a strong motivator for gift giving behavior. Finally, in correspondence with the offline context, negative and aggressive behavior may also be founded in status seeking. While Tokunaga (2010) suggests traditional aggressors and cyberbullies may share the same motivations, few studies have investigated how this behavior fits in the social context of online communities.

When people meet each other in online communities, group membership becomes important and social norms arise. Communication with others online is therefore not merely information exchange. When people meet regularly, they can experience closeness, support, belonging and even intimacy (Boellstorff, 2008; boyd, 2010; Rheingold, 2000). In the context of such communities, often populated by adolescents and their peers, new sets of social norms and ethics will arise (Bradley, 2005). These ethics specifically deal with issues that are relevant in networked publics, such as how to articulate friendship in an online environment, how to behave politely online and how to deal with "drama" and fights on the Internet (boyd, 2010). Social norms online are also highly contextual. What is acceptable in one online community

may be unacceptable in another. O'Sullivan and Flanagin (2003) argued that messages which are perceived as "offensive" in one context, may be considered "normal" in another environment. For cyberbullying, this raises issues about what types of behavior are perceived as cyberbullying in different online communities.

Finally, contemporary teenagers can participate in different communities, providing them with the opportunity to "escape" from real life or to experiment with their behavior in different subgroups. Technological development lays the foundation for different platforms and applications, enabling people to connect to others, in multiple environments, crossing geographic boundaries (Wellman, 2002). Adolescents may seek out the opportunity to engage freely in discussions about the topics of their choice. These could include subjects which are not often discussed in their offline environment, such as gaming or the creative production of pictures and videos (boyd, 2010). Moreover, evidence shows that young people find a certain kind of social support in online communities, which some may lack in real life (Pascoe, 2010; Subrahmanyam and Greenfield, 2008; Wolak et al., 2003). As a consequence, young people who are bullied in an offline or online context, may find support or companionship in an(other) online community. In addition, engaging in multiple online communities may offer the opportunity to experiment with identity (Valkenburg, Schouten, and Peter, 2005). In general, people nowadays are connected to multiple (online) communities, but without feeling the personal involvement and control which characterize traditional communities (Wellman and Hampton, 1999). In terms of social networks, this would noticeably decrease constraint and increase structural autonomy, meaning that individuals have more opportunities because they are connected to others who are unconnected to each other (Mesch and Talmud, 2010). As peer control is restricted to separate communities, users can display certain behaviors in one community, without members from other communities knowing about it. This may have consequences for perpetrators as well as victims of bullying. While perpetrators can go about bullying in one context, people in other communities may not know about their behavior. Likewise, victims can take advantage of this freedom and restrict bullying to one specific context.

3.2. Online Extensions of Offline Networks

While previous approaches focused on online communities, the online interactions among teens can also be studied departing from existing offline social contexts and relationships. Young people mainly use ICTs to communicate with others they know from offline environments, such as their school, neighborhood, leisure activities and family circle (Boneva, Kraut, and Frohlich, 2001; boyd, 2010; Gross, 2004; Lee, 2009; Livingstone, 2009). They talk about issues that concern their everyday lives, such as personal matters and friendship (Boneva, Quinn, Kraut, Kiesler, and Shklovski, 2006; Licoppe and Smoreda, 2005), homework (boyd, 2010; Van Cleemput, 2010), relationships (Subrahmanyam and Greenfield, 2008) and family matters (Kaare et al., 2007). Hence, the online communication among young adolescents is often an extension of their offline lives, grounded in "real world" issues. Research on online interactions can therefore also map the existing relationships in offline environments (such as school) and study how these ties are translated online. Studies already indicate that the strength of a tie (e.g., being "good friends" versus being "acquaintances") seems to have an effect on the frequency of online communication, and the channels that are being used.

Adolescents who know each other better (in the offline context) communicate more frequently, using multiple communication channels. This use of multiple communication media by people who are strongly tied, is labeled “media multiplexity” in the literature (Haythornthwaite, 2005). It has been found in different groups such as academics (Haythornthwaite and Wellman, 1998), university students (Haythornthwaite, 2005; Haythornthwaite, Kazmer, Robins, and Shoemaker, 2000; Ledbetter, 2009; Miczo, Mariani, and Donahue, 2011), young adults (Boase, Horrigan, Wellman, and Rainie, 2006) and adolescent pupils (Van Cleemput, 2010). In the last study pupils reported using more media to communicate with close friends, compared to interactions with pupils who are “just friends” (Van Cleemput, 2010). In addition to using multiple media, the different communication media can be categorized on a uni-dimensional scale (Haythornthwaite, 2005). Group members, who communicate using only one channel, use the same channel (most commonly “face-to-face”). Those who use two channels, tend to add the same channel. This pattern is continued for every additional medium. For teenagers communicating about non-school topics, media are sequentially added in the following order: face-to-face, instant messaging, e-mail, text messaging, mobile calls, and landline calls (Van Cleemput, 2010).

To understand why teenagers choose particular technologies for their online conversations, the characteristics and uses of different media should be considered. For young people a variety of communication means is at their disposal. Communication applications which are commonly used for peer contact include social network sites (e.g., Facebook), instant messaging (e.g., Windows Live Messenger), e-mailing, mobile text messaging and mobile phone calling (Livingstone and Bober, 2005; Livingstone, Haddon, Görzig, and Olafsson, 2011). In choosing the appropriate application for specific communication, teenagers are influenced by different factors, such as spatial constraints, message information and relationship strength (Mesch and Talmud, 2010). Some technologies are mainly used to communicate with strong ties. Mobile phones, for instance, are portable and readily available, allowing teens to coordinate their social activities by sending text messages (Grinter and Eldridge, 2001; Ling and Yttri, 2002). Because of its always-on status, the medium is commonly used for close and intimate relationships (Grinter and Eldridge, 2001). Instant Messaging (IM), as well, suits adolescents’ needs for maintaining and enhancing friendship with close peers (Valkenburg and Peter, 2009). Group identity is strengthened using this technology, as IM effectively simulates time spend with offline friends (Boneva et al., 2006). Other communication channels are used to communicate with a broader range of offline contacts. E-mail is the most prominent example of such technology. First, because teenagers rather associate this medium with “adult” and lengthy conversations (Kim, Kim, Park, and Rice, 2007) and second, because it is used for specific purposes, such as sending documents for homework (Van Cleemput, 2011a). Young adolescents may therefore chose to use e-mail for cooperating with pupils who are not well known, rather than relying on more “personal” media such as IM and mobile phones. Social network sites have emerged as an additional channel of communication, used mainly to support and strengthen weak ties (Mesch and Talmud, 2010; Steinfield, Ellison, and Lampe, 2008; Subrahmanyam, Reich, Waechter, and Espinoza, 2008). In a school context, this can lead to pupils connecting with each other on Facebook because they have met each other before (boyd and Ellison, 2007). While most of the communication channels can be linked to ties of a certain strength, it should be noted that many (well connected) adolescents use multiple channels to communicate, in accordance with media multiplexity (see supra).

When adolescents continue their social interactions in an online context, offline status and social position come into play as well. This idea is reflected in the “rich get richer” hypothesis, which states that socially skilled and extraverted people benefit more from online communication (Valkenburg and Peter, 2007). While results vary depending on the personality trait that was measured, most research finds that extraverts have more contacts online (Bianchi and Phillips, 2005; Kraut, Kiesler, Boneva, Cummings, Helgeson, and Crawford, 2002; Valkenburg and Peter, 2007). Social network analysis confirmed these findings in offline adolescent environments. Van Cleemput (2011b) found that having a higher number of mutual friends at school is related to communication with more fellow pupils by means of instant messaging, as well as mobile phone texting. Similarly, socially isolated adolescents are less likely to use instant messaging and text messaging (Alison Bryant, Sanders-Jackson, and Smallwood, 2006). In summary, the offline position of adolescents in a group also impacts their position in online environments.

3.3. Personal Online Networks

A third approach to online interactions is to study personal networks. From this point of view each individual (ego) has connections with others (alters) who they communicate with. Hogan (2008) describes two ways in which data on personal networks are commonly collected: either by surveying a random selection of participants within a certain population, or by gathering interaction data unobtrusively (e.g., requesting it from service providers or operators). The latter method has been applied for the analysis of mobile phone correspondence (Stoicaa, Smoredaa, Prieurb, and Guillaume, 2010), e-mail networks (Loch, Tyler, and Lukose, 2003) and Facebook data (Lewis, Kaufman, Gonzalez, Wimmer, and Christakis, 2008). While such data is useful to discern patterns in communication networks, usually little cues are available about the content of the interactions or the correspondents’ characteristics. In order to study cyberbullying, user-reported networks may be more informative.

Allowing respondents to select others from different environments provides a broad overview of their communication networks. Whereas studying social interactions in an existing context maps the entire network, user-reported egonet research provides a detailed view of one’s personal contacts (which can originate from any context). In previous research, this approach was used to analyze the strength of online ties (Boase et al., 2006; Mesch and Talmud, 2006), information exchange in a company (Haythornthwaite and Wellman, 1998) and the configuration of different communication relationships (Fisher, 2005; Kim et al., 2007). What the latter study found is that young students mixed relationships from different origins in multiple media, while older workers tended to manage different sets of contacts in different media (Kim et al., 2007). This finding suggests that adolescents’ lives from different contexts come together online. This is certainly the case for communication through popular social network sites, such as Facebook, where teenagers are connected with “friends” from different environments (Livingstone, 2008). While previously youth were able to separate social contacts from school, neighborhood and leisure activities, interaction on Facebook may dissolve those boundaries. Implications for online bullying are discussed in the following section.

4. A SOCIAL NETWORK PERSPECTIVE ON CYBERBULLYING

The present chapter has argued that the social context is essential in studying adolescents' bullying behavior. For cyberbullying, research already offers some cues about the social environment in which the behavior takes place. First, a limited number of surveys studies have asked respondents to indicate from which context they know their aggressors. As a general trend, about half of the adolescents reported being cyberbullied by someone they know in real life (Vandebosch and Van Cleemput, 2009; Ybarra, Mitchell, Wolak, and Finkelhor, 2006). In contrast, the number of youngsters who only know their perpetrator online ranges from 19 to 57 percent (Juvonen and Gross, 2008; Vandebosch et al., 2006; Wolak et al., 2003). These findings indicate that aggressors may originate from multiple contexts, offline, as well as online-only. In the former category peers from school take a prominent position. If the victim and perpetrator know each other, it is highly likely they are attending the same school, or even class (Juvonen and Gross, 2008; Kowalski and Limber, 2007; Smith et al., 2008). For the category of online-only perpetrators, interviews showed that online bullies may either pick completely random strangers, or they may choose specific targets who appear weak (Vandebosch and Van Cleemput, 2008). Second, in terms of social relationships between victims and perpetrators, evidence is more limited. Two studies indicated that over half of the online victims indicate being bullied by the same person offline, suggesting that bullying "extends" in cyberspace (Vandebosch et al., 2006; Ybarra, Diener-West, and Leaf, 2007).

While traditional research was able to touch upon some aspects of social contexts, many issues in cyberbullying are still to be studied, including bully-victim relationships, offline and online positions of perpetrators and victims, influence of online group processes and online subgroups and social norms. For a more thorough analysis of the social context a different angle and methodology are required. We have suggested here that social network analysis provides a suited perspective and toolset to understand bullying behavior in the social sphere. Social network analysis allows researchers to consider social interactions among respondents, such as communicating, being friends or bullying. Possible venues for SNA research in the context of electronic bullying are discussed for the three perspectives discussed previously: 1) online communities, 2) online communication departing from existing offline environments and 3) personal networks of interaction and communication.

4.1. Cyberbullying in Online Communities

In online communities we may expect to find the same processes which explain "real life" bullying. Social status seeking, being one of the main motivators for offline bullying (Sijtsema, Veenstra, Lindenberg, and Salmivalli, 2009), is likely to also affect negative actions online. Social network analysis can be applied to examine this influence, by linking the social status of online community members with their involvement in harassing actions online. Social status, often operationalized as social position, can be measured as the number of positive nominations received from group members. This could include fellow members indicating someone as a contributor on a Facebook-group, a chat partner in a virtual world, or a companion in an online game. Research can elaborate on the online social positions of self-reported victims and perpetrators, as well as group members who are known to defend the victim or assist the

perpetrator. Online bullies may be well connected members who feel supported in their behavior by other members. Alternatively, bullying may not be an effective way of acquiring status in an online context, as the community may rather appreciate “giving gifts” than displaying deviant behavior.

A second process found in groups is the emergence of social norms. In online groups the behavior of participants is guided by certain norms, which may originate from the entire community (e.g., general rules and guidelines) or from subgroups within the community. Different questions can be raised about the role of social norms in online populations and their connection to bullying. First, members who have a positive tie may also share the same behavioral norms. The processes of influence (learning about norms from friends) and selection (selecting friends with the same beliefs) can explain why members who are linked have similar ideas about acceptable behavior online. Social network analysis can be applied to study whether members who are befriended tend to share the same norms. Additionally, analysis of subgroups in the community may show that different subgroups of the population each have their own set of norms. Small variation in normative beliefs within cliques (or other subgroups) and larger differences between cliques would point to subsets of members who share norms. In terms of cyberbullying, network research can assess whether victims (and perpetrators) group together, and whether bully-victim interaction occur within or between different (normative or friendship) subgroups.

4.2. Online Communication by Offline Groups

Another approach, discussed in the previous section, is to study how social relationships and position in an existing offline context influence interactions online. Young adolescents tend to occupy similar social positions offline and online. Those who are socially skilled have more connections in the “real world”, as well as in the cyber context (cfr. the “rich get richer” hypothesis). For cyberbullying, the offline social position of youngsters could be related to their involvement in online bullying. Social network analysis could elaborate on this issue and assess the linkages between offline interactions (such as friendship, popularity or dislike) and reported online victimization, perpetration or bystandership. One social network study departed from an existing school network to predict involvement in cyberbullying (Festl and Quandt, 2011). In this exploratory study two complete school networks were reconstructed (n=409) based on pupils’ reported friendship ties. The friendship network showed that perpetrators, as well as victim/perpetrators are better connected and occupied “bridge” positions, connecting different subgroups (Festl and Quandt, 2011). Quantitative analysis of the data demonstrated that online perpetrators have more “best friends” at school, while victims have less. In addition, Festl and Quandt (2011) identified several “hot spots” of cyberbullying in which victims and perpetrators are closely connected. Comparable research by Wegge, Vandebosch and Eggermont (2013) studied cyberbullying in the context of social networks at school. Figure 2 features a graphical representation of cyberbullying involvement in the mutual best friends network of a school grade. Social network analysis indicated that having a lower number of mutual school friends predicted cyberbullying victimization. This study also demonstrated that adding social network variables contributed to explaining cyberbullying in a school context (Wegge et al., 2013).

A different set of questions concerns patterns of traditional bullying and cyberbullying. While the former approach considered social positions, networks analysis can also focus on

interaction patterns between adolescents. One type of interactions, particularly interesting for this chapter, is bullying and cyberbullying behavior. User reported involvement in (cyber)bullying can be mapped as a social network, providing a detailed overview of who is being cyberbullied by whom (see figure 3). For this purpose, respondents would nominate others who they have been cyberbullied by from an actor list of the studied population. This approach has been applied in a pilot study by Wegge et al. (2013), which studied cyberbullying behavior in an entire grade of secondary school pupils ($n=174$). Results indicated that cyberbullying is a true extension of traditional bullying, i.e., victims were being bullied by the same perpetrators offline and online. Again, this is in line with the idea that offline social attributes impact the online context. While this study has discussed key issues in (cyber)bullying and social relationships, many aspects still remain unexplored. Future areas of focus can include the role of cliques and subgroups, the different perspectives of victims and perpetrators and the relationship with online interactions other than bullying (for instance, being friends on Facebook).

Figure 2. Cyberbullying involvement in a school grade friendship network.

A final set of issues deals with the technologies that offline groups of adolescents use to communicate online. It has been argued that people choose communication channels based on the characteristics of the medium, as well as the strength of ties with the correspondent. When studying online bully interactions as social networks, analysis can elaborate on the technologies used to target specific peers. While different media are used by young people to cyberbully others, research has not yet connected the number and type of channels to victim-perpetrator relations. It may be hypothesized, for instance, that pupils who are merely acquaintances use different media to bully, as compared to friends-of-friends. Additionally, communication channels may affect who is aware of cyberbullying instances. Although few pupils may observe mobile phone bullying, the number of potential bystanders is much higher in bullying on Facebook (Boyd, 2010). Studying the bystander networks can provide unique information

about who is witnessing cyberbullying and how this relates to technologies, as well as victim-bystander relationships.

Figure 3. Patterns of cyberbullying in a school grade friendship network.

4.3. Personal (Online) Networks and Cyberbullying

Besides studying cyberbullying from the perspective of online communities and offline social networks, as discussed previously, SNA can also relate adolescent personal networks to online bullying. The former approach is limited to the study of one specific context, in which all actors provide information about their ties. Because all ties in the network are known, it allows the analysis of entire network configurations. In contrast, the ego network approach is concerned with the actors' personal ties in different environments. It enables respondents to provide information about ties and interactions with any actor they wish to nominate. Interactions can include being friends at school, communicating on IM, being (cyber)bullied, etc. The resulting social networks (and reported characteristics of the alters) can be analyzed to connect personal networks to involvement in cyberbullying.

Analysis could focus on the nature of the personal network, such as network size and the composition of contacts from different environments. In terms of size, it could be expected that youngsters who fall victim to cyberbullying are exposed to a larger network of online contacts as they are generally heavy Internet users (Kowalski, Limber, and Agatston, 2008; Walrave and Heirman, 2009). Alternatively, young adolescents who have suffered from cyberbullying in the past may also shy away from online contacts because of their negative experience. For perpetrators, who appear more central in friendship networks (cfr. *supra*), it can be expected that they are better connected online and have more Facebook "friends" or IM contacts. In

terms of composition, network analysis can assess who victims communicate with online. Victimized youngsters may choose to avoid others from “hostile” environments in which they are bullied (such as school) and direct their communication to peers from a different context (leisure for instance, or even Internet-only contacts). Other issues include the position of perpetrators in victims’ communication networks (What is the frequency and medium of contact? How do incidents affect contact?) and the role of adults in youngsters’ online communication (In whose networks do they appear? How does their presence influence victimization and perpetration?).

Finally, it has been argued that online means of communication, most notably social network sites, merge different “contexts” in adolescents’ lives, which were previously separated. Ego network analysis accommodates the study of personal contacts in different environments. It can assess, from the victim’s point of view, who has performed the bullying, who was a bystander, who responded to the actions etc. Perpetrators, as well as bystanders, may be found in multiple environments. Research can address how online victimization is linked to multiple contexts, as well as to what extent it is witnessed by peers from different settings. In addition, as bullying crosses the boundaries of physical contexts, so may defending behavior. Victims may be asked who has helped them when they were bullied, as to learn in which context defenders may be found. Finally, young people who are cyberbullied may feel inclined to separate peers from different environments, to impede further spreading of the bullying. In this regard, it is relevant to study whether victims use social network sites, for instance, to communicate only with peers from environments in which they are not victimized.

CONCLUSION

Cyberbullying, just like traditional bullying is highly embedded in the social context of young people’s relationships and interactions. The position that youngsters take within a social environment, their belonging to certain groups and subgroups, and the relationships with peers, all affect the patterns of victimization and perpetration in bullying. These contextual factors, as well as the processes guiding them, have already been evaluated and proven useful for explaining traditional bullying (see for instance Huitsing, Veenstra, Sainio, and Salmivalli (2010), Moutappa et al. (2004) and Salmivalli (2010)). In research on cyberbullying, however, such social contextual factors have remained largely unexplored. The present chapter has described how social context matters for electronic forms of bullying as well. Online communication among adolescents is embedded in social groups and takes place among correspondents who inherently have some kind of relationship. In addition, technological means of communication reshape social contexts in terms of possible connections (the emergence of online communities), communication channels (possibilities and uses of different applications), social norms and status (cyber ethics and online popularity) and social boundaries (overlapping environments and Internet-only contacts). The importance of social environments calls for a more contextual examination of cyberbullying, taking into account group processes and social relationships, as well as the specificity of the online context.

It has been argued that social network analysis is highly suited as a perspective and “toolset” to study cyberbullying in adolescents’ social contexts. The basic purpose of SNA is to examine social relationships (ties) between individuals (actors). In this regard, it is well

equipped to analyze the links between cyberbullying and the different interactions and relationships that young people have in offline and online environments. The three approaches presented in this chapter each apply a different research design to elaborate on different aspect. The first suggests that processes which are active in offline groups also drive social interactions in online communities. By studying online communities it relates cyberbullying to online status seeking, (sub)group norm adherence and participation in multiple environments. The second approach focusses on the online communication of adolescent groups who know each other from offline environments, such as school, leisure associations or sport clubs. This perspective would rather consider how social position and bullying involvement in an existing offline context, influences young people's online positive and negative interactions. Finally, the third approach adopts an "ego net" perspective, studying the configurations of people's personal networks in different (offline and online) environments. This design could assess the impact of overall network size and composition on cyberbullying involvement, as well as the overlap between different environments.

In summary, the approaches and questions presented here can be conceived as a research agenda for the analysis of cyberbullying from a social network perspective. This particular type of analysis concerns not only the application of new methods and tools, but also, perhaps primarily, a fundamentally different perspective. Social network analysis is grounded in people's social relationships and takes actor interactions as its main focus of analysis. As cyberbullying essentially involves actors interacting within a broader set of social relationships, it is crucial to understand the contextual factors which lead to involvement in such negative behavior. The proposed approaches promise further academic insight into the issue of cyberbullying, which may ultimately also help educators and organizations to act upon negative behavior within specific social contexts.

Chapter 71

CONCEPTS OF BULLYING: DEVELOPMENTAL AND CULTURAL ASPECTS

Peter K Smith*, PhD and Claire P Monks, PhD

Department of Psychology, Goldsmiths, University of London,
Department of Psychology and Counselling,
University of Greenwich, London, England

ABSTRACT

This chapter considers the origins of the term ‘bullying’ and historical changes in the definition of bullying, leading to contemporary research definitions in terms of agreed criteria. It next considers how we can assess the actual working definitions or criteria used by pupils, teachers, parents or others concerned with bullying, in different countries. Developmental changes in the understanding of bullying are reviewed, and contrasted with developmental changes in bullying behaviours. In the final section, cultural similarities and differences are reviewed. Again two aspects are considered: the words used for bullying-related phenomena in different countries and their meanings, and the behavioural manifestations of bullying.

INTRODUCTION

The Encarta World English Dictionary (1) gives the following definition of bully: an aggressive person who intimidates or mistreats weaker people, mid-16th century origin uncertain, probably from Middle Dutch boele ‘lover’, originally ‘sweetheart’, then ‘fine fellow’, ‘blusterer’.

Within the research literature, a widely used definition of bullying (2) specifies that bullying:

- is an aggressive act
- with an imbalance of power (victim finds it difficult to defend him/herself)

* Corresponding Author’s Email: pss01pks@gold.ac.uk.

- has some element of repetition (these things can happen frequently)
- can be physical, verbal or indirect

Bullying is thus seen as a subcategory of aggressive behaviour, but of a particularly vicious kind, since it is directed, often repeatedly, towards a particular victim, who is unable to defend himself or herself effectively. The attacks are mostly unprovoked and are intended to hurt the other. Victimised children may be younger, less strong or simply less psychologically confident. The bullying child or children use this behaviour to inflict harm, gaining psychological gratification, status in the peer group or, at times, direct financial gain by taking money or possessions.

HISTORICAL ORIGINS OF THE STUDY OF BULLYING

The concept of 'bullying' first came to prominence in England through Thomas Hughes' (1857) book *Tom Brown's school days*, in which Tom and some of his friends are tormented by Flashman and his gang at Rugby school: 'Flashman was about 17 years old, and big and strong of his age ... a formidable enemy for small boys'. The Head of House says: '... there's a deal of bullying going on. ... Bullies are cowards ...'.

However the scientific study of bullying has its main origins in Scandinavia, and especially the work of Dan Olweus. A school doctor, Heinemann, introduced the Swedish term *mobbning* in a book '*Mobbning – Gruppvåld bland barn och vuxna*' (1972). This was borrowed from the ethological term 'mobbing', or 'all against one', describing a collective attack by a group on an individual (here, often of another species). Olweus then used the term in his book '*Forskning om skolmobbning*' (1973), translated as '*Aggression in Schools: Bullies and Whipping Boys*' (1978). His later book '*Mobbning – vad vi vet och vad vi kan göra*' (1986) uses the same term, and was the basis of his most well known book '*Mobbning i skolan*' (Swedish version), '*Mobbing i skolen*' (Norwegian version) and '*Bullying at School: What We Know and What We Can Do*' (English version) (all 1992/1993), which has been translated into many languages.

'Mobbing' carries the connotation of the 'group vs. one'. However, Olweus soon rejected this: "It is questionable how common all-against-one situations really are in a school setting ... it is perhaps rather unusual for the whole class (the boys or the girls) to be united in an intense collective activity ... mobbing by very small groups is the more frequent type in our schools" (3); and later "Data from our Bergen study ... indicate that, in the majority of cases, the victim of bullying is harassed by a small group of two or three students, often with a negative leader. A considerable proportion of victims, some 25-40 percent, report, however, that they are mainly bullied by a single student" (4).

Olweus also designed a self-report questionnaire to assess bullying in schools, incorporating a definition as indicated above. Shorter but similar definitions are (5): "Bullying is repeated oppression of a less powerful person, physical or psychological, by a more powerful person"; and (6): "The systematic abuse of power". A fuller definition is (7): "Bullying involves a desire to hurt + a harmful action + a power imbalance + (typically) repetition + an unjust use of power + evident enjoyment by the aggressor and generally a sense of being oppressed on the part of the victim".

The earlier work on bullying (3) only mentioned physical and verbal kinds of bullying (reflecting the main kinds of aggression described at the time). However contemporary definitions stress a broader range of forms that bullying can take. Only in the 1990s was attention drawn explicitly to indirect, psychological and relational forms of aggression, and also of bullying (8,9). In the 2000's, a new form of bullying, often called cyberbullying and using mobile phones and the internet, has become prominent (10).

Another recent term is 'bias bullying' or 'prejudice driven bullying'. This refers to bullying on the basis of group rather than individual characteristics, and would include racial harassment, faith-based bullying, sexual harassment, and homophobic bullying.

The modern definitions of bullying clearly embrace more than school contexts. There is a growing literature on workplace bullying, and bullying in prisons; there is less research on bullying in the community. There is some work on sibling bullying, but this behaviour in the home context is often referred to as 'abuse'.

ASSESSING DEFINITIONS AND CRITERIA USED, AND THE CARTOON TASK

Whatever definition researchers decide on, children and young people, and even parents and teachers, may not necessarily share that definition. Two main approaches have been used in the study of how bullying is defined outside the research community: basically, 'recall' and 'recognition' tasks. In 'recall' tasks, participants are asked to define bullying, say what they think it is, and/or give examples of bullying. For instances of this approach, see (11,12). While this tells us what participants readily call to mind, it does not necessarily represent their full range of knowledge. For example, children primarily give physical or verbal examples of bullying, and rarely indirect ones, even though in recognition studies most will agree that indirect examples can be bullying. Recall tasks are also not efficient at showing important age changes, such as the greater breadth of definition in younger children (see below, age changes).

For these reasons, many researchers have used 'recognition' tasks: for example a participant is given a vignette and asked if this is bullying. A particularly developed methodology is the cartoon test (13). The cartoon test can be used to give an empirically based understanding of how words such as 'bully' (or similar words in English or other languages) are applied, and facilitates comparisons across age, gender, or experience; and across cultures, as the cartoons are stick figures with universal applicability.

The test uses a set of 25 cartoons, illustrating different social situations that might or might not be bullying. The situations vary in terms of relevant definitional parameters, such as type of aggression, number of aggressors, relative power, intent of the perpetrator, provocation of the victim, repetition and negative effect on the victim. Themes such as racism, sexism and discrimination on the basis of disability or sexual orientation, are included, plus a number of neutral or prosocial cartoons as controls. To implement the test, each term is taken in turn, and the participant is required to either include or exclude each cartoon as examples of the term they are presented with, by scoring, or sorting in a pile, under the heading: 'this is X' or 'this is not X' (where X is the term being currently considered; such as bullying; harassment; teasing). For each cartoon, the percentage of participants who include it as part of their

'definition' of each term, is computed. A meaning profile for each term can then be constructed, based on which cartoons load heavily on it.

There was little gender difference in the understanding of terms on the cartoon task (13), even though other evidence shows that the style of bullying behaviours between males and females differs. However there were substantial age changes (see below), and also variation of meaning amongst the terms used in different countries (see below: cultural differences). Although this has not yet been done, the cartoon test (or similar methodology) could be used to track changes in meaning over time. For example in English, the term bullying has traditionally referred to mainly physical and verbal forms of attack; but, over the last decade, it is come to include more indirect and relational forms of aggression, such as spreading nasty rumours, and social exclusion.

AGE CHANGES

Understanding of bullying

There is good evidence of age-related changes in perceptions of bullying. These might be developmental (e.g., related to changing cognitive capacities and greater experience in older children or adults); or might be historical (e.g. reflecting predominant usage at the time a person was growing up and at school). It is possible to make some plausible suggestions about each of these, although cohort-sequential studies would ideally be needed to do this with confidence.

A number of studies show that until around 8 or 9 years of age, pupils use the term 'bullying' quite broadly, to cover all nasty kinds of behaviour even when no imbalance of power is involved (14,15). This appears to reflect a simple 'good-bad' evaluative dimension used by younger children. Researchers (16) compared children's perceptions of aggression, withdrawal and likeability items around 6, 9 and 12 years; using multi-dimensional scaling, they found a shift with age from a simple evaluative dimension and low cohesiveness of clusters at 6 years to a more complex separation of clusters with an additional active-passive dimension by 12 years.

Eight and 14 year-olds were compared on the cartoon task (13). Examining the structure of the cartoon set using multidimensional scaling, the solution for the 8 year olds produced only two clusters: Non-aggressive and Aggressive items. The solution for the 14 year olds showed five clusters: Non-aggressive; Physical aggression (an even-handed dispute or a provoked retaliation); Physical bullying (with power difference between the disputing parties in terms of size, strength, number and consistency); Verbal (direct+indirect); and Social exclusion.

How about adults? Children may tell an adult (parent, teacher) something about bullying, but how do adults understand this? This may depend, at least in part, on the significance adults give to children's words like 'hurt', 'calling names', and 'bullying'. It is therefore very important to assess what adults mean by 'bullying' (for instance) in order to evaluate what probability children have to be understood.

The definitions of 'bullying' held by children (4-6 years and 8 years), adolescents (14 years) and adults (parents) in England were compared, using a shortened version of the cartoon task (omitting extortion, sexual or racial discrimination, homophobic bullying or bullying about a disability, considered inappropriate for use with young children) (17). The findings, some of which are shown in table 1, showed that the two child groups (4-6 years and 8 years) had a

similar understanding of the term ‘bullying’, but were over-inclusive in their definition of bullying. For example most thought that fighting (without an imbalance of power) and that not letting someone play on one occasion was bullying (see table 1).

Adolescents and adults had a more differentiated concept of ‘bullying’ than younger children. In addition to distinguishing between aggressive and non-aggressive behaviors, they also distinguished physical and non-physical acts (such as name-calling, rumor spreading and social exclusion). They took into account the imbalance of power between the aggressor and victim, and the repetition of the behavior.

Table 1 indicates that few 14 year-olds and adults thought that fighting (without an imbalance of power) was bullying, whereas the majority considered fighting (with an imbalance of power) bullying. Noteworthy is that adults were less likely to consider social or relational aggression as bullying. Table 1 shows that fewer adults than pupils considered not letting someone play every day, or spreading rumors, to be ‘bullying’. This may be related to the more recent work in schools to include these forms of bullying within anti-bullying programs. It is possible that parents’ understanding of bullying derives from when they were at school, at a period when bullying was mainly viewed as describing verbal or physical aggression (see section above). These findings highlight the potential for miscommunication between teachers/parents and pupils who do not have a shared understanding of the concept of ‘bullying’. This may lead, on the one hand, to teachers/parents being seen by children as not responding to or even condoning certain types of ‘bullying’, and children seen by teachers or parents as over-reporting ‘bullying’.

Using the full cartoon set, the understanding of ‘bullying’ held by parents in England was examined (18), as well as similar terms in four other countries. It was found that parents tended to focus on physical acts of aggression and viewed ‘bullying’ as meaning severe physical aggression; and they were unlikely to consider severe social exclusion as bullying. Teacher and pupil responses to the cartoon task were investigated in Italy (19). There was high agreement on physical acts, but pupils were more willing to include social exclusion and gender based exclusion as aggressive or ‘bullying’ acts, than teachers.

Table 1. Some age differences in use of the term ‘bullying’. Adapted from Monks and Smith (17)

Cartoon	4-6 yrs (N=99)	8 yrs (N=40)	14 yrs (N=40)	Adult (N=40)	Chi-square (3df)
X and Y don’t like each other and start to fight	81.8	90.0	15.0	7.5	111.76***
X won’t let Y play today	72.7	87.5	45.0	27.5	41.03***
X starts a fight with Y who is smaller	72.7	92.5	97.5	92.5	19.52***
X never lets Y play	65.7	90.0	75.0	45.0	19.78*
X tells nasty stories about Y	76.8	90.0	85.0	52.5	18.34***

AGE CHANGES

Behaviors related to bullying

Until the late 1990s research into bullying behavior focused on children and adolescents over the age of 8 years, probably as a result of the widespread use of self-report questionnaires

such as the Olweus Questionnaire. More recently, research has examined these behaviors when children first enter school or preschool, from the age of about 4 years (20). It is clear that some children behave aggressively towards their classmates from very early on. The aggressive behaviours exhibited by young children differ from those identified in older children and adolescents. They can be aggressive physically, verbally and/or relationally; however, they more often use direct, confrontational methods, rather than indirect methods (such as rumor spreading) (21). Indirect aggression and bullying is more characteristic of older children and adolescents (8). Young children's aggression towards their peers also differs from bullying as observed in older pupils in terms of the repetition of these attacks. One key feature which distinguishes bullying from aggression is the repetition of the behaviour by the same aggressor to the same recipient (5). But although the aggressive behavior of young children shows some stability over time, with the same children behaving aggressively towards their peers, it is not the case that they repeatedly target the same individual(s); they appear to be targeting different children on different occasions. This means that victimization is a relatively common experience during early childhood, but tends to be a one-off for many children (21,22). As these behaviors do not meet the criteria to be defined as bullying, researchers have tended to label them as peer-victimization rather than bullying. However, it is thought that they may be the precursors to bullying. It has been suggested that the widespread and somewhat indiscriminate victimizing of a large number of peers may reflect the aggressors trying to identify the most susceptible victims, those who would withdraw or cry perhaps, within a new peer group (23). Others have noted that young children find it difficult to identify withdrawn behaviour in their classmates, which may result in aggressive children being less discriminating in their aggression (24). In addition, it has been proposed that this low stability of the victim role may be a reflection of the less fixed social hierarchy present among younger children as compared with those in middle childhood and adolescence, meaning that those children who are being victimized during early childhood may find it easier to escape this role and further victimization (25). Young children's broader definition of the term bullying may reflect their more limited cognitive capabilities, in terms of making subtle distinctions between behaviours in terms of repetition and an imbalance of power. Alternatively, it may reflect the actual experiences of children at this age, with a lack of repetition of being the target of aggression by peers being commonplace.

CULTURAL DIFFERENCES

Terms used for bullying

When one tries to translate the term bullying in other languages, there is generally no equivalent word that covers fully the meaning of bullying. This can even be the case in other English speaking countries, such as the USA, where the term victimisation has mainly been used, at least until recently. In Latin languages (e.g., French, Italian, Spanish, Portuguese) several terms exist, but none a very good match. Researchers in Poland (26, p.265) have commented that "The Polish language has no exact equivalent of 'bullying' ... one has to talk about 'acts of aggression', 'violence' or 'oppression'". This is quite a general issue. Some common words that are approximate equivalents of English 'bullying' are shown in table 2

(13,27,28, and Rubina Hanif, Farzaneh Pahlavan, Jorge Srabstein, Zehra Ucanok, and Shraddha Vora, personal communications).

In fact, as the research area on bullying expanded, and public concern has grown, in some countries the English word 'bully' or 'bullying' has been adopted or adapted. In Germany now the term 'bully' is used as well as 'täter'. In Spain, 'bullying' is an increasingly recognised term. And in Italy the term 'Il bullismo' has been introduced, as in Fonzi (ed.) (1997), *Il Bullismo in Italia*; Menesini (ed.) (2000), *Bullismo: Che Fare?*; and Genta (ed.) (2002), *Il Bullismo*.

A first empirical attempt to study the meaning of different terms cognate to bullying was made with the cartoon task (13). A survey of children's definition of bullying across different countries was carried out. Stick figures were used so as to avoid issues of clothing, which might vary by culture, and to avoid suggesting any particular ethnic group or skin colour. Identical pictures were used across all cultures. Each cartoon had a caption in the native language. The English captions constituted a reference set. In each other country, these captions were translated into the native language used by participants, and back-translated to ensure fidelity of meaning. Then terms for bullying and social exclusion were selected, and checked with focus groups of pupils to ensure these were widely used and understood. The sorting task was then given to a minimum of 20 boys and 20 girls each aged 8 and 14 years old, in 14 countries: Austria, China, England, France, Germany, Greece, Iceland, Italy, Japan, Norway, Portugal, Spain, Slovenia and Thailand.

In each country, 1 to 5 terms were examined in relation to the cartoons, and specifically to the 5 main clusters of cartoons described above. The meaning of each term could be expressed as average percentage scores within each cluster of cartoons (rather than 25 individual scores). The similarity or difference in meaning between any two terms could then be assessed by comparing their percentage profiles across the five clusters. A hierarchical cluster analysis was conducted over a total of 67 terms, in order to show which terms had similar meanings.

Six main groups or clusters of terms were identified: 19 terms that are generally higher on physical bullying, verbal and social exclusion than on physical aggression; these terms tend to be closest to the definition of bullying, and do indeed include the English terms 'bullying' and 'picking on', and the Italian term 'prepotenza'; six terms that score most highly on social exclusion, for example Portuguese 'rejeicao'; seven terms that all score much more highly on verbal (direct+indirect) than on physical bullying or social exclusion, including the English term 'teasing'; 19 terms that are weighted most highly on verbal (direct+indirect), but moderately on physical bullying, and less on social exclusion, including the English terms 'harassment', 'intimidation' and 'tormenting'; three terms that are only weighted highly on physical aggression and physical bullying; and 13 terms that load highest on either physical aggression or physical bullying, but moderately on either verbal (direct+indirect) and/or social exclusion, including the Italian terms 'violenza' and 'aggressivita'.

The cartoon methodology proved easy to administer and to be a relatively interesting task to do but obviously the results are limited by the situations presented. In particular, the set of 25 cartoons does not represent some situations found in eastern countries such as Japan or South Korea, including severe or whole class-based social exclusion; nor does it include cyberbullying, an increasingly common form. An expanded set of 40 cartoons has been developed, and has been piloted in England, Iceland, Canada, Japan, mainland China, Hong Kong, South Korea, and recently in Turkey and Pakistan (29).

Table 2. Words used as possible equivalents or translations of “bullying” in different countries (romanised equivalents used for some languages)

Country	Some Terms Used
England	Bullying Harassment Teasing Intimidation Tormenting Picking on
Norway	Erting Mobbing Plaging Krangling
Sweden	Mobbning Utfrysning Kränkning
Denmark	Mobbe Skoleboeller
Iceland	Einelti Radast a Hrekkja Skilja ut undan Strida Taka fyrir

This data can increase the sensitivity of researchers to variations in meanings between terms when used in questionnaires, surveys and reports; and hence in interpreting cross-national comparisons.

CULTURAL DIFFERENCES

Behavioral differences in bullying

The nature of the language we use to describe ‘bullying’ interacts in a complex way with the nature of ‘bullying behaviours’ that actually occur in different cultures. In general, we find

out about what happens by asking about it: 'How often have you been bullied this term?'. 'Bullied' has to be translated appropriately. A number of such studies have been carried out: see reviews in (28) and for explicit cross-national comparisons using similar methodologies (30,31). These studies show a lot of structural similarities. For example, boys are generally more numerous in the 'bully' category but not necessarily in the 'victim' category; boys are more likely to engage in physical bullying; rates of being a victim (but not bullying others) decline with age; bully/victims are most at risk of psychological problems. However these studies often show different percentages of bullying across different countries. These might reflect real behavioural differences; or they might reflect differences in interpreting the term 'bullied'; or in meaning differences between the related concepts primarily used in that country.

For example in Italy, children involved in bullying (bullies or victims) have been found to range from 45% to 37% in primary school; the corresponding percentage in England is about 27%, in Portugal around 20%, in Spain 18%, in Japan 11%, and in Norway 9% (28). Are these differences due to actual differences in the amount of bullying, or do they depend on the fact that Italian, English, Portuguese, Spanish, Norwegian and Japanese children are responding to different linguistic terms or cultural concepts? Evidence that part of the problem relates to linguistic terms has come from Italian research. The term 'prepotenze', widely used as the appropriate term for 'bullying' in Italian questionnaire studies, has a broader meaning profile than 'bullying', as shown by the cartoon test; it includes physical aggression as well as physical bullying, for example. Italian researchers have found that the use of different terms to translate 'bullying', significantly affects the incidence rates obtained (32).

Although we can try to bypass linguistic differences by relying on observed behaviors, this is problematic in the case of bullying. For example, a definition give above (7), includes 'a sense of being oppressed on the part of the victim'. Even though it is not so explicit in other definitions, whether something is 'abuse' or 'oppression' will depend in part on how the recipient or 'victim' of the act, views the situation. If they take the act as playful; or if they take the act as justified in some way; then it would be difficult to argue that this is bullying, oppression, or an abuse of power. But of course we can only know how the recipient views the act, by asking them – either directly, or by responding to a standard questionnaire on bullying.

It is thus difficult to distinguish behavioural differences from linguistic differences. As an example, consider the differences between 'ijime' and 'bullying', which has received considerable attention. In Japanese, 'ijime' is defined slightly differently from 'bullying', with more emphasis on the psychological and group nature of the attack (33). The cartoon test shows 'ijime' to have a stronger loading on verbal/indirect than on physical bullying (in contrast to 'bullying'); it does not load highly on social exclusion, probably because the original cartoon test did not include the kinds of group-based social isolation that 'ijime' can involve (29).

Kanetsuna and colleagues (34, 35) have examined the kinds of situation in which high school pupils say that ijime (in Japan) or bullying (in England) occurs, using corresponding questionnaires and interviews in the two countries. They found some significant differences. In Japan, pupils reported ijime as most likely to come from pupils that they knew well, of similar age and often within the classroom; in England, pupils reported bullying as often coming from pupils they did not know well, often older, and often in the playground. However, we need to bear in mind that the Japanese pupils have been asked about ijime. It seems that an older pupil using their position of power to take advantage of a younger pupil, might not be considered as ijime, even though it might be considered as bullying in England. The expanded cartoon set has one cartoon where the rest of the team won't let a pupil take part in a competition, even though

s/he is one of the best players, because s/he is from a lower year group. 81% of 14 year old English pupils say this is bullying; but only 29% of 14-year old Japanese pupils say this is *ijime*. What this example shows is that some (ab)use of power by older pupils might happen in Japan, as in England, but not be reported as *ijime*; inevitably, reports of bullying or abusive behaviour will reflect what is thought of as abusive, and the related terms to describe this, as well as any actual differences in behaviours.

The Japanese example is not unique. A somewhat similar pattern of difference comes from studies of 'wang-ta' in South Korea, by Kwak, Koo and colleagues (36,37). 'Wang-ta' has a very similar profile to 'ijime' on the cartoon test, and also seems to occur between pupils who know each other (e.g., former friends). Within a classroom context this can mean the whole class shunning one pupil. It can take the form of even more severe social exclusion, where another term 'jun-ta' refers to the whole school labelling the victim and shunning that person. Not surprisingly, many such victims show psychiatric symptoms and may have to receive special schooling (37).

Japan, and South Korea, may both be considered as more collectivist societies than England or most western industrialised countries; a more collectivistic culture may imply a greater possibility of concerted whole-group (e.g., whole-class) norms emerging, which could at times be aggressive – thus the possibility of severe whole-class aggression and shunning of a victim. (This possibility is also exacerbated because, unlike the situation in many western countries, secondary school pupils largely maintain the same home-base classroom for all lesson topics). In addition, Japan and South Korea may be considered more hierarchical, with more respect for older persons, including older pupils, such that (ab)use of power by older persons will be more likely to be seen as legitimate and not abusive (38).

In summary, although many similarities emerge in cross-national studies of school bullying, there are also important differences. Such differences may be actual differences in behaviour, perhaps due to societal differences in dimensions such as individualism-collectivism, or hierarchy. More prosaically, they may be due to differences in schooling arrangements (age bands, lunchtime arrangements, extent of home-room class teaching). And, there are also differences in conceptions of abuse, and abuse of power; and differences in the words available to describe these. In addition, all of these factors can and do change through historical time.

CONCLUSION

It may be unfortunate that 'bullying' has come to occupy a certain privileged position in the scientific community, due to the dominance of English-language journals and publications. We have a range of terms with both subtle and sometimes obvious differences in meaning (as defined by situations which may be thought of as having considerable cross-cultural similarity). In this sense, the social construction of meaning, and its cultural and temporal variability, becomes apparent and explicit. This is not a reason for abandoning the scientific endeavour, but certainly a warning for care and circumspection in the interpretation of results across age groups, languages, cultures, and historical periods.

ABSTRACT

Over the past 25 years, concern has been growing for children's bullying. We now recognize that bullying is wrong and hurtful. Research has fuelled a growing understanding that persistent bullying may be an indication of significant psycho-social problems. In this paper, we describe our longitudinal research on the development of bullying, examine risk factors associated with diverse pathways of bullying, and consider intervention strategies to address problems among children and youth who bully.

INTRODUCTION

Over the past 25 years, there has been a growing concern for children's bullying. We now recognize that bullying is wrong and hurtful. Research has fuelled a growing understanding that persistent bullying may be an indication of significant psycho-social problems (1). In this chapter, we describe our longitudinal research on the development of bullying, examine risk factors associated with diverse pathways of bullying, and consider intervention strategies to address problems among children and youth who bully.

Bullying has been defined as negative actions -- physical or verbal -- that have hostile intent, are repeated over time, and involve a power differential between the child who is bullying and the victimized child (2). The nature of bullying changes as children mature. Bullying can start in early childhood and persist through the school years, peaking during the school transitions (3,4). From early adolescence, new forms of aggression, carried out from a position of power, emerge. With developing cognitive and social skills, children become aware

* Corresponding Author's Email: pepler@yorku.ca

of others' vulnerabilities and of their own power relative to others. With development, bullying diversifies into more sophisticated forms of verbal, social, cyber, sexually- and racially-based aggression.

Recent research has begun to uncover the complexity in bullying and the diversity among children who bully: some have serious problems with aggression and self regulation; others are socially skilled and central members of the peer group who have learned to acquire power through bullying (5-7). We have investigated the diverse pathways in bullying with a longitudinal study of 871 students (466 girls; 405 boys) beginning when students were 10 to 12 years of age and following them for seven years through the end of high school (8). Using statistical analyses that reveal clusters of children who develop in similar ways, we found four different pathways that reflected students' reports of bullying their peers over the seven years. One group (10%) reported consistently high levels of bullying from late elementary through high school (high bullying group).

A second group (13%) reported bullying at about the same level as the high group in late elementary school, but their levels dropped to almost no bullying at the end of high school (desisting group). A third group (35%) reported consistently moderate levels of bullying throughout the years (moderate bullying group). The remaining 42% of the students almost never reported bullying (low bullying group). Given these diverse groups of children and their different levels of involvement in bullying, we were interested in examining what factors differentiated the four groups as these indicators provide direction for prevention and intervention strategies.

How to understand bullying: Developmental-systemic perspective

Through our research, we have come to understand bullying as a relationship problem that requires relationship solutions. Our observational and survey research reveals that bullying problems arise from complex interpersonal dynamics rather than simply from a child's problems with aggression (8-11). In considering factors that may place children at risk for bullying their peers, we must take a developmental-systemic perspective to examine both individual children's characteristics as well as the quality of children's relationships. Consequently, in our longitudinal research on the development of bullying, we studied several individual characteristics including moral disengagement, physical aggression, and relational aggression as potential risk factors associated with bullying others.

In our research, moral disengagement was measured with questions on: being mean to others, cruel to others, not being trustworthy, being manipulative, and lacking guilt. From a systemic perspective, we were interested in the quality of students' relationships with their parents, as well as with peers. We asked students about their relationships with parents in terms of trust, conflict, and monitoring.

We asked students about their relationships with peers in terms of conflict with peers and susceptibility to peer pressure. We were also able to assess the degree to which other youth in the students' peer groups also reported bullying and hence formed a peer context for bullying.

Diverse developmental pathways and profiles of risk

Low bullying group

Given that bullying is wrong and hurtful, it is encouraging that almost half (42%) of the students in our study very seldom reported bullying others from late elementary school through to the end of high school. Consistent with gender differences in other forms of aggression, the proportion of girls in the low bullying group was almost double that of boys (53% and 29%, respectively). Students who followed the low bullying pathway reported the most adaptive individual and relationship factors. Compared to the moderate, desisting, and high groups, they were least likely to report moral disengagement, and physical and relational aggression. The low group also reported the healthiest relationships. They had more trust and less conflict with parents who were in touch with their lives (monitoring). Their peer relationships were also healthiest, with low conflict and susceptibility to peer pressure, and fewer friends who themselves bullied. In considering the risk factors for the groups involved in high, moderate, or desisting bullying, we used the low bullying group for comparisons. In a sense, we consider this group the “gold standard”: these youth have developed the critical relationship skills and understanding to avoid using their power aggressively with peers and to maintain positive relationships within the family and peer group.

High bullying group

At the other end of the spectrum is the group of youth who report persistently high levels of bullying from late elementary school (ages 10 to 13 years) through the end of high school (ages 14, 15, 16, and 17 years). Within this group, there was a marked gender difference: the proportion of boys who fell onto the high bullying pathway was four times higher than the proportion of girls (16% and 4%, respectively). This pattern suggests that bullying is highly atypical for girls. Although their numbers are lower, girls who engage in chronic bullying experience a wide range of psychosocial problems (11). In late elementary school, children who are on course for persistently using their power aggressively presented with high levels of individual and relationship problems. They were significantly higher than the low group on moral disengagement, as well as on physical and relational aggression. These problems persist into high school with the same group differences on individual risk factors associated with bullying. When we consider relationships in these children’s lives, a similar pattern of risk emerges. In late elementary school, they are significantly different than the low bullying group on low trust and high conflict with parents, and their parents’ monitoring is lower. With peers, the high bullying group reports significantly higher conflict and susceptibility to negative peer pressure, and they associate with more peers who bully compared to the low group. As they continue on the high bullying pathway, all of these risk patterns persist into high school.

Moderate bullying group

In many respects, there is cause for concern about youth who report moderate, but consistent levels of bullying over the late elementary and high school years. Gender differences are also found in this trajectory group: 41% of boys fell into the moderate bullying group, compared to 30% of girls. These data suggest that a persistently moderate level of bullying is somewhat normative for boys, even though bullying is wrong and hurtful. Youth on the moderate bullying pathway reported individual problems that were similar to the high bullying group. In elementary school, they were significantly higher than the low bullying group on

moral disengagement, physical and relational aggression. These patterns of individual risk persisted into high school. It is in their relationships that we see a difference between the patterns of the high and moderate bullying groups, primarily within the family context. Although they reported significantly lower trust and monitoring than the low bullying group in both the late elementary and high school years, there was no difference between the moderate and low groups' reports of conflicts with their parents. In relationships with peers, the moderate bullying group differed from the low bullying group in reports of conflict and in associating with bullying peers at both time periods. In the early adolescent years, the moderate bullying group did not differ from the low group on susceptibility to peer pressure; however, they reported succumbing to peer pressure in the adolescent years.

Desisting bullying group

The desisting group is interesting because it gives us a glimpse of what might be important to enable youth to move beyond using their power aggressively as they mature. In contrast to the high and moderate bullying groups, a similar proportion of boys and girls fell onto the desisting pathway (14% and 13%, respectively). When in late elementary school, the desisting bullying group reported engaging in bullying at a level similar to the high bullying group. During this stage, they appear to have many of the same individual and relationship risk factors as the high and moderate bullying groups. Compared to the low bullying group, they reported more moral disengagement, and more physical and relational aggression. Their relationships with parents were lower on trust, higher on conflict, and they reported that their parents were less aware of their comings and goings than the low bullying group. Their relationships with peers were similarly troubled in late elementary school: they had more conflict with peers and their friends were more likely to bully compared to the low bullying group. Similar to the moderate bullying group, in early adolescence these youth reported low susceptibility to negative peer pressure that did not differ from the low bullying group.

The picture for the desisting group changed substantially in high school, when their reports of bullying decreased. Positive developments were evident in all domains – the desisting group no longer differed from the “gold standard” low bullying group on any of the individual risk factors, nor on the quality of their relationships with parents. They were no longer higher in conflict with peers and seem to have stopped associating with friends who bully. The only risk factor that remained was susceptibility to peer pressure.

Our longitudinal research reveals important variations in the development of bullying and in associated risk factors – there is not a standard profile of children who bully. To assess and intervene with children who bully, we need to consider a range of individual strengths and weaknesses, as well as the relationship contexts in which children develop (12,13). In the next section, we consider the prevention and intervention strategies to support the healthy development and relationships of children who bully.

Interventions for bullying: Developmental-systemic perspective

Our research has led us to recognize bullying as a relationship problem, leading to a basic tenet for prevention and intervention strategies: A relationship problem requires relationship solutions. Within the relationship context of bullying, children who bully learn how to use power and aggression to control and distress others. Prevention and intervention strategies need

to provide children who bully with the critical skills and contexts to transform their relationships from ones in which they use their power aggressively to those in which they use their power positively. Our work draws heavily from a positive youth development perspective (14). Within this positive perspective, we avoid labeling children as “victims” or “bullies,” but take a broader perspective on their strengths and challenges. The goal of interventions with children who bully is to enhance their relationship capacity and to promote healthy relationships in the present in order to lay the foundation for healthy relationships throughout the lifespan. Youth who are persistently high on bullying require intensive clinical support; those on the moderate and desisting trajectories require support tailored to their needs until they learn the skills and orientations necessary for healthy relationships.

To achieve relationship solutions, children who bully need to be provided with formative, rather than punitive consequences – interventions that provide a clear message that bullying is unacceptable, build awareness, skills, empathy, and insights, and provide alternatives to bullying. Research points to many domains for intervention at the individual and relationship levels. Support for children with bullying problems can be delivered through school-based and clinical programs, but lessons are also required on a moment-to-moment basis in the home, classroom, and community.

Individual risk factors

At the individual level, moral disengagement emerges as a strong risk factor for persistent bullying. Children who bully their peers fail to understand or ignore the critical message that bullying is wrong and hurtful. Bandura (15) described moral disengagement as a lack of self regulation regarding moral conduct. Youth on the high and moderate bullying trajectories consistently reported problems in being mean and cruel to others, not being trustworthy, being manipulative, and lacking guilt. These youth require specific support in recognizing that bullying is wrong, in appreciating the rights of others, and in regulating their own emotions and behaviors in order to reflect and act on what is right and wrong.

Bullying is a form of aggression; therefore, it is not surprising that other forms of aggression are related to persistence in bullying. The use of aggression may relate to two basic problems: the lack of emotional and behavioral regulation and the need for power and status. The first problem of self regulation might differentiate the high and moderate groups, although our research does not specifically address this issue. Children who persist in bullying at a high rate may not have learned the lessons of self control and social skills critical to healthy relationships.

It is important to support these youth in learning to control their anger, developing social understanding, and solving social problems in adaptive ways. The second problem is that children who bully have learned to use their power aggressively: they are asserting social power through aggression.

The challenge is to redirect these children’s leadership potential from the negative strategies of bullying to positive leadership skills and opportunities. These children require support to find positive ways of gaining power and status among peers.

Family and peer relationships

Children first learn how to relate to others in the family context and then in the broader contexts of peers, schools, and communities. If these relationships are strained, children fail to develop the attachments, skills, insights, and trust that are essential for positive relationships. We found that relationships with parents are low in trust and high in conflict for both the high and moderate bullying groups. There is also low monitoring, which is an index of the quality of the relationship and youths' willingness to disclose details of their lives to their parents (16). A prevention focus on family relationships is critical because without a foundation of healthy relationships within the family, youths are limited in their capacity to achieve healthy relationships outside the family. Parents may need support in developing a positive perspective of their children and in finding strategies that are positive and constructive.

Youth who fall on the high and moderate bullying pathways also experience strained relationships with peers. They have more conflict with friends and are embedded in groups with peers who also bully. High conflict with peers will arise if a youth does not possess adaptive problem solving skills and/or is associating with others who lack these skills. Because of the strong reinforcement that deviant youth provide each other for negative behavior (17), reducing the extent to which a youth associates with troubled peers may be a critical strategy to address problems of bullying.

Children who exhibit persistent problems of bullying at a high or moderate rate are learning the "effectiveness" of using their power aggressively to control and distress others. Left unchecked, these relationship patterns may carry forward into dating aggression and into marital abuse, child abuse and workplace harassment in adulthood. Bullying is wrong and hurtful at any age. Children who persistently bully have failed to learn critical relationship skills and attitudes. They experience a wide range of physical and mental health problems and are in need of focused support to enable them to move on to healthy relationships – the foundation of well-being throughout the lifespan.

Chapter 73

SCHOOL BULLYING: ITS NATURE AND ECOLOGY

Dorothy L. Espelage*, PhD and Lisa De La Rue, MA

Department of Educational Psychology University of Illinois,
Urbana-Champaign, Illinois, United States of America

ABSTRACT

Recent youth suicides only highlight a persistent problem in schools – bullying and sustained peer victimization. Being a target or victim of bullying has long been recognized as having short- and long-term psychological effects on children and adolescents across the world today. School bullying is one of the most significant public health concerns facing children and adolescents. Objective: Involvement in the social phenomena of school bullying is often explained as emerging from a wide range of risk and protective factors within the social-ecology of youth. The social-ecological model posits that bullying behaviors are shaped by various interrelated contexts, including individual characteristics, family, peers, and the school environment. Methods: Research is reviewed to highlight the correlates of bullying involvement across these contexts using social-ecological and social-learning frameworks. Meta-analytic studies are reviewed on the short- and long-term impact of bullying involvement and efficacy of bullying prevention programs. Specific recommendations for prevention planning and future research efforts are provided. Conclusions: Bullying is a multi-faceted issue, which is best understood in the larger social context in which it occurs. Individual characteristics of students contribute to bullying involvement when students have families that promote violence, teachers that ignore or dismiss bullying, schools that have negative climates, and students who hang out with friends who bully. These social contexts need to be targeted in bully prevention programs to reduce bullying and peer victimization in schools.

INTRODUCTION

School-based bullying emerges from a complex interplay among individual characteristics of bullies, victims, bully-victims, and bystanders, their family experiences, their school

environment, influences from their peers, and larger community factors. In this paper, research is reviewed to highlight the correlates of bullying involvement across these context using social-ecological and social-learning frameworks. Specific recommendations for prevention planning and future research efforts are provided.

Involvement in the social phenomena of school bullying is often explained as emerging from a wide range of risk and protective factors within the social-ecology of youth (1). The social-ecological model posits that bullying behaviors are shaped by various interrelated contexts, including individual characteristics, family, peers, and the school environment (2). Also, because bullying is seen as a form of aggression that initiates and is maintained through learning, modeling, and socialization, social learning (3) theoretical frameworks have been used to understand school bullying (1). Bandura's (4) social learning theoretical framework emphasizes that the context in which individuals learn is influenced by the reciprocal relationship among the biological and psychological characteristics of the person, his/her behavior, and the environment.

DEFINITION AND ASSESSMENT

With few exceptions, the definition that dominates the bully research literature has been adopted from Professor Dan Olweus's pioneering scholarship on bullying in Europe. He posited that "A student is being bullied or victimized when he or she is exposed, repeatedly and over time, to negative actions on the part of one or more students" (5). It is important to consider the components of this definition as we move forward. It is evident from this definition that bullying involves negative actions that are repeated. In other variations of this definition it is implied that bullying is intentional and involves a power differential between the victim and those who are perpetrating the bullying. Growing evidence, however, suggests that students' own definition of bullying deviates substantially from this widely adopted definition.

More specifically, Vaillancourt and colleagues in Canada asked students ages 8 to 18 years ($N = 1767$) to provide their own definition of bullying, and only 1.7% included the notion of intentionality, 6% mentioned repetition, and only 26% mentioned a power imbalance, however, 92% did indicate behaviors that are negative (6). In a randomized design, students presented with a definition indicated less bully victimization than students who responded to just behavioral indicators of bullying without a definition, suggesting that presentation of the definition impacts reporting rates. More recently, Cook and colleagues indicated in a meta-analysis of 153 studies that the association of bully status (bully, victim, bully-victim) and individual and contextual outcomes were not moderated by whether a study provided a definition of bullying, or provided only behavioral descriptors of aggression (7). Taken together, it is imperative that the next generation of bullying research explicitly tests the components of the bullying definition in order to determine the most salient aspects of intentionality, repetition, and a power differential. Finally, bully assessments must go through extensive cognitive testing to determine what aspects of a definition, if any, students are using when responding to follow-up questions and how prevalence rates and correlates differ when other forms of aggression are assessed with a definition.

A closer examination of definitional and assessment issues will be instrumental as research moves to expand our understanding of bullying and victimization that is occurring through cell phones and computers. Cyberbullying, or technology aggression research is in its infancy, thus,

all disciplines must contribute to this emerging literature by conducting studies on this topic to determine which theories of school-based bullying translate or do not translate to the computer-based bullying.

PREVALENCE

Recent youth suicides only highlight a persistent problem in schools – bullying and sustained peer victimization (1). Being a target or victim of bullying has long been recognized as having short- and long-term psychological effects on children and adolescents across the world today (see meta-analysis, 7). Bullying is one of the most significant public health concerns facing children and adolescents (8). Involvement in bullying among elementary and middle school students is quite prevalent with students assuming roles such as bully, victim, bully/victim, and various bystander roles (7,9). Worldwide incidence rates for bullying in school-aged youth range from 10% of secondary students to 27% of middle school students who report being bullied often (10). Current estimates suggest that nearly 30% of American students are involved in bullying in one of these capacities (11).

Specifically, findings from this nationally representative sample indicated that among 6th to 10th graders, 13% had bullied others, 11% had been bullied, and 6% had both bullied others and been bullied. Bullying involvement has also been implicated as a predictor of school shootings. In the United States, an investigation was commissioned in 2000 by the Secret Service; family and friends of students involved in 37 incidents of targeted school shootings and school attacks between 1974 and 2000 were interviewed. Researchers discovered that 71% of the perpetrators had been victims of bullying (12). It appears that retaliation on the part of former victims is spanning across the globe with the recent school shooting in Rio de Janeiro, Brazil (<http://www.bbc.co.uk/news/world-latin-america-13003419>).

Individual differences. Certain individual characteristics heighten risks for being victim of bullying. Boys are more often victimized than girls (7,13), although this depends somewhat on the form of victimization; whereas boys are more likely to experience physical bullying victimization (e.g., being hit), girls are more likely to be targets of indirect victimization (e.g., social exclusion) (14). One of the few studies that addressed influences of race on bullying found that Black students reported less victimization than White or Hispanic youth (11). Other factors increase one's likelihood of bullying others. Boys are more likely to bully peers than girls (15), and individuals with behavioral, emotional, or learning problems are more likely to engage in bullying than peers (16).

Bullies, particularly male bullies, tend to be physically stronger than peers. Juvonen, Graham, and Schuster (17) found Black middle school youth more likely to be categorized as bullies and bully-victims than White students. Another study found somewhat more Hispanic student bullying reports than for Black and White youth (11).

ACADEMIC AND PSYCHOSOCIAL CORRELATES

Psychosocial Correlates. In the most comprehensive meta-analysis of the correlates of bully involvement among children and adolescents, Cook and colleagues (7) found overlapping and distinct individual correlates across 153 studies of bullies, victims, and bully-victims.

Overall, bullies have elevated externalizing behaviors, social competence and academic challenges, negative attitudes and self-cognitions; whereas victims have elevated internalizing behaviors, negative self-related cognitions, and lower social skills. In addition, bully-victims have elevated co-morbid internalizing and externalizing behaviors and negative attitudes about oneself.

Academic outcomes. Recent studies are supporting what we have suspected for years. Being a target of bullying can have a major impact on school engagement, achievement, and test scores. For example, Glew and colleagues (18) found an association between bullying victimization and low academic achievement. More recently, Glew and colleagues (19) found that for each one-point rise in the grade point average of 7th, 9th, and 11th graders in an urban public school district, the odds of being a victim, versus a bystander, decreased by 10% (19).

A study of 930 6th graders in the first year of middle school found that students who were bullies, victims, or bully-victims showed poorer school adjustment (e.g., doing well on schoolwork, getting along with classmates, following rules, doing homework) than their uninvolved peers over three assessments into the end of the 7th grade (20). It stands to reason that the prevalent nature of bullying is preventing many very talented children and adolescents from achieving their full academic potential.

FAMILY CORRELATES

Research has suggested that bullying behaviors (bullying and bully/victim) and victimization are differentially associated with various family-level factors. A thorough examination of the extant literature indicated that bullies have elevated family conflict and lower parental monitoring, and are highly influenced by negative home environment (7).

Specifically, among a European sample of middle school children, families of bullies displayed low cohesion compared to families of victims and bully/victims, especially among siblings (21). Moreover, bullies and bullies/victims report receiving less parental social support than their peers who are uninvolved in bullying (22). Evidence also suggests an association between bullying and an authoritarian parental style and conflict/disagreement with parents (23), while others have cited associations between bullying and lack of warmth and parental indifference/permissiveness toward children (24). Perceptions of family functioning are also related to bully perpetration.

Among a sample of Australian 11 to 16 year olds, bullying was associated with poorer psycho-social family health, less positive relations with parents in families where both parents were present, and low parental emotional support (25). In families where only mothers were present, bullying was related to negative attitudes towards their mother for boys only (26,25).

In a sample of American middle-school children, significant differences were found in the prevalence of bullying and victimization by siblings among bullies, victims, bullies/victims, and those not involved in bullying (27). Nearly one-third of students who reported bullying their peers were also bullied by their siblings (29.03%). More than half of those who bullied their peers (56.45%) reported bullying siblings. In addition, research has shown that sibling conflict is associated with teacher ratings of aggression and high rates of sibling conflict are associated with less social competence and more aggression (28).

Generally, children who witness or experience the perpetration of violence in the home may identify with the perpetrator and/or learn that violent and aggressive acts are appropriate

behaviors, especially when the behavior goes unpunished (29,30). Additionally, an explanation consistent with Bandura's social learning theoretical framework would posit that because students experience and witness certain behaviors in the familial setting, they are likely to perform those behaviors when motivated to do so in the school setting. When children witness aggressive behavior on the part of their parents, social learning theory would propose that some children model the behavior of the aggressive parent by becoming bullies whereas others model the behavior of the parent who was aggressed against by becoming victims of bullying.

Indeed, several studies found that domestic violence is more likely to occur in families of bullies (31,30,32) victims of bullying (33), and bully-victims (34) than in families of those not involved in bullying. Child maltreatment has also been associated with bullying involvement (30,35), although more research needs to be conducted on this connection.

PEERS

Consistently, bullying perpetration is found to be influenced largely by peer norms and peer socialization (36,37,38). In addition, scholars suggest that bullying prevention programs that emphasize and encourage bystander intervention are likely to be effective in reducing bullying rates in schools (39,40,41,42). These researchers encourage bystanders to either report an incident of bullying or to confront students who are bullying other students. It is believed that as more bystanders intervene then bullying will become less prevalent and a more positive school climate will result. Data often suggest, however, that adolescents rarely intervene to assist victims. Further, self-declared bullies and bystanders sometimes report feeling sorry after bullying their peers though they rarely intervene in bullying episodes (43). O'Connell, Pepler and Craig (44) videotaped 1st through 6th graders ($n = 120$) during recess. The researchers found that 54% of peers spent their time reinforcing bullies by passively watching, 21% actively modeled bullies, and only 25% intervened. Older boys (grades 4-6) were more likely to join actively with the bully than were younger boys (grades 1-3) and older girls. Younger and older girls intervened on behalf of victims more often than older boys. Additional analyses of these videotapes showed that peers were present during 88% of bullying episodes, but only intervened 19% of the time. The researchers indicated that 57% of the interventions effectively stopped the bullying (45).

More recently, Rigby and Johnson (41) attempted to elucidate the characteristics of youth that are willing to intervene in bullying situations. Four hundred Australian primary and secondary students viewed a videotape of a bullying situation and were subsequently asked what they would do if witnessing the bullying. Multiple regression analysis indicated that greater willingness to intervene was associated with being younger, having rarely or never bullied others, having been victimized, and having a positive attitude toward victims. In addition, students were more likely to intervene if they believed their friends expected them to support victims. Similarly, Gini and colleagues found that empathy was associated with defending a victim only for boys, not for girls (46), and attitudes supportive of victims were found for younger adolescence and among girls (47). Consistent with Rigby and Johnson's study, Pozzoli and Gini (48) found that perceived positive peer pressure to defend a victim interacted with personal responsibility to predict defending. That is, students who held moderate or high levels of personal responsibility were more likely to defend a victim if they perceived their peers to hold a positive view toward defender behavior. Recent studies of early

adolescents suggest that cognitive and affective dimensions of empathy differentially predicted willingness to intervene in bullying situations (49). More specifically, Gini and colleagues (49) found that bullies had similar rates of morally competent (cognitive dimension) behavior as victims and defenders, but bullies had lower morally compassionate or caring (emotional dimension) than victims or defenders. Pöyhönen and colleagues (50) found that defending was associated with vicarious understanding (emotional dimension) of victims, rather than a cognitive understanding of the victim.

Finally, only one empirical study has considered how willingness to intervene in bullying situations is potentially influenced by the amount of bullying among a student's peers or within their friendship group using nested, peer-level data (51). Some of the extant literature had included the application of social network analysis to test similarity of friends on measures of bullying perpetration (52,53,54) but none had assessed how bullying perpetration among friends negatively influences adolescent's willingness to intervene over time. Espelage and colleagues (51) examined the associations among gender, empathy, attitudes toward bullying, willingness to intervene, and bullying within peer groups in a sample of 6th and 7th grade students ($N = 346$). The authors identified peer groups via social network analysis using NEGOPY (55) and examined peer group influence through multi-level modeling. Greater bullying perpetration within one's peer group was highly predictive of less individual willingness to intervene, suggesting that any prevention efforts to address bystander or defender intervention must first reduce the level of bullying with peer groups.

TEACHERS, ADMINISTRATORS AND PARAPROFESSIONALS

Teachers, administrators and other staff all influence the social climate of their schools, playing a prominent role in the education of their students. While teachers and students share the same environment, research has shown that there are often differences in perceptions of bullying prevalence, which then has implications for intervening and addressing bullying problems. The ability for teachers to identify incidents of bullying amongst students is influenced by a number of factors. As children get older and transition to middle and high school the way bullying is presented changes. Likely due to developmental trends, physical forms of aggression give way to more relational and social forms of aggression as children grow older. Teachers are more effective at identifying bullying behaviors among elementary school children, which tends to be more physical in nature, and have greater difficulty identifying bullying behaviors in adolescents, which tends to be more relational (56). Relational aggression may be more difficult for teachers to identify as it can include social exclusion and can often be done in ways that do not have the same overt behaviors that physical aggression includes. Teachers' attitudes towards the severity of bullying are also related to this transition from more physical forms of bullying to more social and relational aggression. Teachers have rated physical bullying as more serious compared to verbal bullying (57). These attitudes then carry over to how likely individuals are to intervene.

Teachers are less likely to intervene when bullying is of the social exclusion type. The level of sympathy and to what extent teachers view students as victims is a factor. Teachers tend to have less sympathy for victims of social exclusion and are therefore less likely to get involved, and even if they do intervene they will utilize more lenient interventions (57). Furthermore, this

willingness to intervene may also change, as students get older. Teachers may be more willing to redirect younger children, but may not feel as comfortable doing so with older students.

Student characteristics as perceived by the teacher can also impact how bullying is viewed. Teachers may hold views about certain students, which makes it difficult for the teacher to recognize when the student is a victim of bullying. Students who teachers identify as assertive and well adjusted are less likely to be perceived as victims of bullies (58). The attitudes and beliefs that teachers have regarding bullying is important to consider as these beliefs permeate the classroom atmosphere and influence the feelings students have. These beliefs also influence the behaviors of students, both the bullies and victims.

CLASSROOM FACTORS

While bullying starts as a dyadic interaction between a bully and a victim, it is best understood in the broader social context in which it occurs (59). The broader context includes the school, classrooms, and the individuals who engage in these locations, including teachers, students and staff. Teachers play a unique role in the classroom. While they are not directly a part of the peer networks of their students, teachers serve as a connection to other settings and to other adults (60). Teachers can provide a strong influence as they guide their students in academic activities and interactions with peers, setting a tone for what is appropriate. Teachers play a central role in how their classrooms are organized and managed, which then influences the peer ecology (60). Research has demonstrated that teacher's management of the class has a strong relationship with bullying. Classroom management influences bullying both directly, and indirectly via the social structure of the class (61). Therefore, not only does classroom management have direct implications for the prevalence of bullying, but also has an effect on the relationships and social norms of the class, which then influences bullying behaviors.

Teachers attitudes and beliefs about bullying influence the way they manage their classrooms. Kochenderfer-Ladd and Pelletier (62) looked at attitudes teachers had regarding bullying and how that influenced how teachers intervene with elementary age students. Those teachers, who believed that students would not be bullied if they asserted themselves, indicate they would advise their students to stand up for themselves (62). However, when teachers believed that bullying was a normal part of student interactions, they were less likely to intervene. In this view, victims of bullies are not seen as being as adversely impacted by the bully's behaviors. It may be that teachers who do not feel sympathy for a victim may feel that getting involved is unnecessary (57).

Craig, Henderson, and Murphy (63) argue that teacher attitudes towards bullying, as well as their likelihood to intervene, is influenced by contextual and individual factors. When bullying is physical, as opposed to verbal, in nature, and is witnessed, teachers are more likely to view the incident as bullying and view it as more serious and worthy of intervention. Furthermore, when verbal aggression and social exclusion were witnessed these behaviors were more likely to be labeled as bullying (63). Therefore, the views that teachers take and their subsequent actions are directly influenced by them witnessing the event.

The norms of a classroom also influence how children treat each other. In addition, classroom factors influences how victims of bullies are treated by their peers. When reactions to bullying and discipline are lacking or inconsistent in a classroom, this can set up an

atmosphere of tolerance for bullying behaviors. In classrooms where aggressive behaviors are more accepted there tends to be higher levels of aggression (64). Ignoring incidents of social exclusion and relational aggression may be even more common. When teachers ignore social exclusion, they are likely to send an inappropriate message that this type of bullying behavior is tolerated and even permitted (57). This casual attitude can also make victims feel that teachers are uncaring or unable to protect students from bullying.

Teachers can influence the dynamics of their classrooms, encouraging a more egalitarian structure. Classrooms in which the social power is more evenly distributed foster a more pro-social and less hostile environment (64). Aggressive students tend to be less popular in classrooms where students are more equal to each other, as opposed to classrooms where students have unique roles and places in the social hierarchy respective to their classmates. In classrooms where students have unique roles, aggression may be seen as tool for students to maintain their position or to move to alternate positions (64). Being conscious of social hierarchies and power differentials can allow teachers to structure activities and lessons in a way that promotes a decrease of these disparities.

While creating a more egalitarian classroom environment has been shown to decrease concerns with bullying, it can be difficult to achieve in practice. Teachers tend to do well in identifying the most popular and salient groups in a class, but have more difficulty identifying less popular groups (60). Additionally, the social atmosphere, and the status hierarchies in the classroom may change with age. In primary school classrooms (grades one to four), the social structure in a classroom may be more flexible as compared to secondary school classrooms (grades five and beyond). In primary grades, the social hierarchies observed are less stable, in that children at the higher or lower ends of the hierarchy can change their position over time. This more flexible social structure in the younger grades may create situations in which bullies target many different students without a constant focus on one student, as victims can move more freely to peer interactions that have more favorable outcomes (65). Whereas secondary school classes tend to have stronger hierarchical structures, which may explain the lower prevalence but higher stability of victims seen in secondary schools (65). In this case, it is more difficult for students on the lower end of the hierarchy to move and interact with different peers. Additionally, in secondary schools directing aggression to an already disliked peer (low status) appears to be more normative than in primary schools (65). Shifting these norms is a goal that teachers can try obtain through classroom setups and activities.

SCHOOL STRUCTURE

The location of where bullying takes place varies with the age of students. For elementary school students, bullying tends to take place on playgrounds, in cafeterias and classrooms, whereas for older students in addition to the cafeteria and classrooms, hallways and locker rooms are also a source of concern (56). Being aware of areas on school campuses that can increase risk for students can be an effective tool for school staff wanting to intervene in incidents of bullying. It has also been noted that when the student-to-teacher ratio increases, there is an increased risk for victimization (66). While it is not necessarily large schools that create an increased risk (67), when teachers are accountable for a greater number of students they may not have the resources or abilities to diligently intervene on behalf of all the students.

SCHOOL CLIMATE AND ETHOS

A disordered school environment will make it more difficult for teachers to effectively manage their classrooms. This disorder also has implications for the prevalence of bullying. Bradshaw and colleagues (66) found that students within the same schools share similar experiences regarding the perceptions of their school and the appropriateness of using aggression in response to frustrations. Students shared similar perceptions regarding their school environment. However, even though teachers and students share this same environment, their perceptions regarding the school atmosphere and the prevalence of bullying may not always be the same. Teacher reports of the prevalence of bullying are often lower as compared to student reports (58).

Past research has suggested that many teachers may be unaware of the rate of bullying and the extent to which students are victimized. Teachers and school staff tend to underestimate the numbers of students who are victims (56). As a result, teachers may miss opportunities to intervene. According to Pepler et al. (68), 84 percent of teachers reported that they intervened nearly always or often to stop bullying, while only 35 percent of students reported that teachers' intervened. Bradshaw and colleagues (56) also found large discrepancies between staff perceptions of how frequent bullying occurred and student reports of victimization. While these discrepancies may be a result of teachers not being fully aware of the bullying that is occurring in their schools, it may also partly be a factor of students not wanting to report incidents of bullying to teachers and staff.

Students may not go to teachers and staff for support as they might feel reporting the bullying will make the situation worse (56). The advice that students receive from adults, while well intentioned, may not provide them with the resolution they hoped for. For instance, suggestions to "ignore the person" may not be the most helpful advice (69). Additionally, students may also be afraid to report episodes of bullying to teachers out of fear that retaliation will ensue (69).

While students may not seek help, teachers and staff can provide cues to students regarding what types of behaviors and attitudes are accepted in the school. When teachers and other school staff tolerate, ignore, or dismiss bullying behaviors they are conveying that bullying behaviors are acceptable within the school (58). This also has implications for the victims of bullies as they may begin to internalize these beliefs. This can also go in the opposite direction, where school personnel convey to the students that these behaviors are unacceptable. When teachers are able to "intervene in a timely, consistent, and decided manner their efforts are usually effective" in addressing the actions of the bully and the needs of the victim (62, p. 432). Schools should reflect strong disapproval for aggressive behavior, bullying, and social exclusion, and this intolerance should be clearly communicated to students so as to discourage these behaviors (57). This type of school climate will also provide support for victims as they are more inclined to feel supported by their school, teachers, and other staff.

Many of the prevention efforts aimed to reduce bullying assess ways in which teachers can approach situations within their classrooms and provide them with tools to intervene and effectively manage bullying (62).

META-ANALYTIC STUDIES OF BULLYING PREVENTION AND INTERVENTION

Despite a long history of published studies on what predicts bullying involvement in school-age children and adolescents (70,36), systematic evaluations of large-scale prevention programs are only now appearing in the literature. In 2008, a meta-analytic investigation of 16 studies published from 1980-2004 yielded disappointing results regarding the impact of anti-bullying programs (71). This meta-analysis included data from over 15,000 students (grades Kindergarten to 12) in Europe, Canada, and the United States. Positive effect sizes were found for only one-third of the study variables, which primarily reflected favorable changes in knowledge, attitudes, and perceptions of bullying. No changes were found for actual bullying behaviors. These authors indicated in a tentative fashion that school bullying interventions showed modest evidence of enhancing student social competence, self-esteem, and peer acceptance. In addition, it appears that programs shifted in a positive direction teachers' knowledge of effective practices and efficacy of intervening and responding to incidences at school.

Ttofi, Farrington, and Baldry (72) simultaneously conducted a larger meta-analysis that included more studies. In a report for the Swedish National Council for Crime Prevention, they evaluated 44 bullying intervention studies. Results indicated that bullying and victimization were reduced by 17-23% in experimental schools compared to control schools. Ttofi et al. found that reductions in bullying were associated with classroom rules, classroom management, parent training, increased playground supervision, home-school communication, classroom rules, classroom management, and the use of training videos (72). Further, there was a dosage effect; the more elements included in a program, the greater likelihood of reducing bullying. There is sadly, a huge gulf between research and practice in bullying prevention and intervention work. We believe that the next generation of bullying scholarship needs to address the problem from scholars inside and outside of education, and move beyond a focus solely on individual children, but attempt to change the contextual variables that are promoting bullying in our society.

Despite these empirical efforts, what we know and what we can learn about bullying and peer victimization is changing as rapidly as the contexts are changing in which children are embedded. This dynamic proliferation of attention to bullying and peer victimization calls for a continuation of research programs that push the science and practice of bullying research into the next phase. A sample of areas that could benefit from direct prevention and intervention focus include:

- (1) Examining the role of neuroscience in understanding the impact of bullying victimization on child development and inability for youth to engage academically. Only recently has research emerged on the impact of peer victimization on brain functioning (6).
- (2) Incorporating innovative computer science tools and techniques to supervise and track teachers in their efforts to implement school-based bullying prevention programs with fidelity as outlined by developers. Bullying programs are only as good as their implementers. Teachers are the best to implement these programs in their classrooms; however, they have many demands on their time and are likely to drift in their ability

to adhere to bullying lesson implementation. Indeed, the recent meta-analyses (72) suggest that implementation level moderates the efficacy of school programs.

- (3) Developing better observational methods from communication, engineering, and computer science to collect complex observational data on playgrounds, classrooms, etc., where bullying occurs at the highest frequency. Self-, teacher, and peer-reports of bullying all have their validity and reliability issues and generally all fail to assess the dynamic and interactional nature of bullying; thus, observational methods need to be developed that are cost-effective and efficient in examining the interpersonal dynamics of bullying.
- (4) Adapting bullying prevention programs to address diversity in sexual orientation, race/ethnicity, and immigration status. Very little research has focused on the effectiveness of “generic” bullying prevention efforts with subgroups, such as LGBT youth, or ethnically diverse populations.
- (5) Bullying perpetration develops and is supported through a peer norm that promotes bullying and a peer norm that discourages assisting the victim (36,51,73). Given the importance of modifying peer group attitudes in the direction of bystander intervention, prevention programs need to be developed that target the peer group dynamics, attitudes, and behaviors.

CONCLUSION

School bullying is a concern for many students and is an experience that is prevalent in countless schools. It has been recognized that both victims and bullies experience both short-term and long-term psychological effects (74), including academic and psychosocial problems. Bullying is a multi-faceted issue, which is best understood in the larger social context in which it occurs. This includes an examination of individual characteristics, family conditions, peers, and the school environment.

Research has explored many aspects of bullying and its consequences, and future research is hoped to expand on areas that are not as well understood. Furthermore, the changing nature of the world in which children live, including the expansion of technology in their lives, requires that research considers and explores new areas of potential conflict and concern. Moving these research efforts to practice is imperative to inform prevention and intervention programs that can effectively intervene with bullying. Taking into consideration the complex nature of bullying, such efforts may be best suited with a focus on the broader context in which children interact, as opposed to intervening with children solely on an individual level.

ABSTRACT

Parents are often concerned about repeated conflicts between their daughters and sons. However, there is little empirical research of sibling bullying. In this chapter we conduct a review of existing studies of sibling bullying. Are there any associations between sibling bullying and peer bullying at school? What are the consequences of sibling bullying? Is there good justification why sibling bullying has been so neglected in research? *Method:* Studies of sibling relationships were reviewed. Four quantitative studies were identified that report on both sibling and peer bullying. *Results:* Sibling bullying is frequent with up to 50% involved in sibling bullying every month and between 16-20% involved in bullying several times a week. Experience of sibling bullying increases the risk of involvement in bullying in school. Both, bullying between siblings and school bullying make unique contributions to explaining behavior and emotional problems. There is a clear dose-effect relationship of involvement of bullying at home and at school and behavior or emotional problems. Those involved in both have up to 14 times increased odds of behavior or emotional problems compared to those involved in only one context or not at all. *Conclusions.* The empirical evidence is limited and studies are mostly cross-sectional studies. Nevertheless, the review suggests that for those victimized at home and at school behavior and emotional problems are highly increased. Sibling relationships appear to be a training ground with implications for individual wellbeing. Strengthening families and parenting skills and increasing sibling support is likely to reduce bullying and increase wellbeing.

INTRODUCTION

Sibling relationships are generally the most enduring relationships in a lifetime (1-3). By middle childhood children spend more time interacting with siblings than with parents(4). Siblings play an important role in each other's lives as companions, teachers, and caregivers (5-6). Through their relationship and their interactions with each other, siblings significantly contribute to each other's development and adjustment. According to Brody (7), siblings can either have a direct (i.e., related to child-sibling interactions) or an indirect (i.e., related to one child's impact on parents and therefore on the siblings) effect on each other's development. The social ties build in sibling relationships can have wide ranging influences. Studies found that positive quality of sibling relationship and interaction can facilitate the acquisition of skills that are important in cognitive and social development (8) (9). More specifically, it has been found that positive sibling relationships help children develop social skills and provide emotional support (10), protect children from other family adversities such as adverse life events (11) or marital conflicts (12) or poor peer relationships (13). On the other hand, negative sibling relationships intensify adjustment problems (14) and may create long-term adverse effects.

Physical aggression between siblings has been reported to be the most common form of family violence and is experienced by up to half of all children in the course of a year (2). Some (15) reported that 40% of the children whose parents they interviewed had hit a brother or sister with an object during the preceding year, and 82% had engaged in some form of violence against a sibling. Others report that that between 30% and 98% are physically attacked or victimized by their siblings during a year (16). In many families aggression between siblings is frequent and a source of great concern to parents (17) and is the most prevalent form of family violence(2). Similarly, up to a quarter of children become victims of violence from non-sibling peers, most frequently at school (18). As the example shows violence between children in the family or children in the nursery or school is viewed differently than violence between adults or of an adult to a child (1). The same act seems to have different meaning if it occurs between siblings or peers compared to adults. If committed by an adult it would readily be labeled an assault and treated as a crime. In contrast, if committed by one child against another it is often described as scuffles, fights, or altercations. It is so common that few people regard it as deviant behavior and within families it is often ignored.

Thus, the quality of the social ties between sibling relationship may have positive, negative or even unanticipated consequences. For example, unanticipated consequences of good sibling relationships are that if one sibling becomes obese, the chance that the other will become obese increases by 40% (95% CI, 21 to 60). (19). Thus even a positive relationship can have unanticipated negative outcomes.

In the following we will explore the extent, the reasons and the consequences of sibling bullying. Is sibling bullying different from bullying between non-sibling peers? Are there any associations between sibling bullying and peer relationships at school? Are the consequences of sibling bullying less overwhelming, less injurious or less psychologically harmful than of peer bullying? Is there good justification why sibling bullying has been so neglected (2)?

SIBLING BULLYING

Bullying victimization refers to children being exposed repeatedly and over time, to negative actions on the part of one or more other children who are or perceived to be stronger (20). It is intentional harm doing and systematic abuse of power (21). Bullying can be physical or direct including verbal abuse, hitting, kicking, destroying others' belongings or blackmail. In contrast, relational bullying refers to deliberate social exclusion of children such as ignoring, excluding them from games or parties, spreading gossip or humiliation (22). Direct bullying is more frequent at younger ages and decreases with age. It has been suggested that relational bullying increases in adolescence. Those subjected to both direct and relational bullying on a regular basis appear to be at the highest risk for adverse outcomes (23-24).

Surprisingly, when abuse researchers report about violence between siblings they very rarely use the term "bullying" although it is often clear that they are referring to bullying as defined above (25). Sibling relationships have similar characteristics that are associated with bullying in the peer group. Unlike friendships and similar to peer relationships in the classroom, sibling relationships are involuntary, i.e., children cannot choose their siblings they live with but they were born into these relationships. Siblings are rarely equal in terms of age, size, and physical or psychological strength; therefore there is an imbalance of power. Furthermore, the direct or indirect attacks are not single events but are frequent and repeated. Finally, similar to peers confined in the same group, siblings spend considerable amounts of times together often in the absence of an adult, which provides significant opportunities for the bullying of one sibling by another. Time spent together leads to familiarity that can breed contempt. This means they know exactly how to provoke or upset their siblings (17). Sibling interactions are emotionally charged relationships defined by strong, uninhibited emotions of positive, negative and sometimes ambivalent quality (7).

STUDIES OF SIBLING BULLYING

A range of previous studies, mainly in the 70s and 80s, looked at family violence and reported on physical attacks or sexual abuse between siblings (25-26). Others have used retrospective designs on sibling aggression between siblings (27). Thus there has been awareness of violence between siblings but these studies did not include the repetitive nature of intentional harmful acts that defines bullying but included one-time events (16,28).

Table 1 provides an overview of four studies that systematically investigated bullying between siblings. The studies are from the USA (29), Israel (26), Italy (30) and the UK (31). All studies are cross-sectional and assessed both sibling and peer bullying with self-report scales completed by the children.

In addition, three of the studies investigated behavior or emotional problems, and some additionally wellbeing (31); personality and other sibling relationship areas (30) or loneliness (29). All four studies studied children in early adolescence, i.e., between 10 and 15 years of age and sample sizes ranged from 195 to 2163 adolescents; between 87% and 100% of these adolescents had siblings.

Table 1.

Authors	Country	Sample	Age	Instruments ¹	Sibling Bullying	Peer Bullying	Associations with Behavior or Emotional Problems																
Duncan (1999)	USA	Total N: 375 Females: 178 Males: 194 With siblings 336 (89.6%)	Mean: 13.4 years (7-8 graders)	- Adapted Peer Relations Questionnaire (Rigby & Slee, 1992) - Multiscore Depression Inventory for Children (MDIC) (Berndt & Kaiser, 1996) - Children’s Loneliness Questionnaire (CLQ – Asher & Wheeler, 1985)	Total N: 336 Not involved: 186 (55.4%) Involved: - Victim: 10 (3%) - Bully: 49 (14.6%) - Bully/victim: 91 (28.6%) (classifications: pretty often/very often)	Total N: 373 None: 207 (55.5%) Victim: 60 (16.1%) Bully: 72 (19.3%) Bully/victim (34 (9.1%) (Classification: Pretty often/very often)	As most siblings were bully/victims, all subgroups collapsed into Sibling involved in Bullying (N: 150) Siblings involved: - had higher scores in all MDIC-scales e.g. Anxiety or overall depression. - higher loneliness scores in CLQ - a significant sibling involvement by peer involvement interaction was found: - those who were bully-victims at school and involved in bullying at home had the highest level of psychopathology - those not involved at home or at school had the lowest psychopathology and loneliness																
Wolke & Samara (2004)	Israel	Total N: 921 Females: 473 Males: 448 Jews: 449 Arabs: 472 With siblings: 898 (97.5%) Median Number of siblings: 3	Mean: 13.7 years SD: 0.9 years (7-9 graders)	- Adapted Bullying Questionnaire (Olweus, 1991; Wolke et al. 2000) - Assesses physical, verbal and relational bullying - Strength and Difficulties Questionnaire (SDQ, Goodman, 2001)	Total N: 898 Victim: 152 (16.9%) - Physical only: 3.3% - Verbal only: 6.6% - Both: 5.4% (Classifications: every week/several times a week)	Total N: 921 Victim: 145 (15.8%) Bully/bully-victim: 120 (13.1%) (Classification: every week/several times a week)	- SDQ factor analysed and standardized for sample. ¹ please see the original articles for references instruments used in studies.

The median number of siblings was 1 in the UK (32.8% had 2 and 15.9% 3 or more siblings) (31) while the median was 3 siblings in the Israeli Jewish or Arab families (26). Only the UK study (31) provides detailed information on the family composition with just over half the adolescents (57%) living with both biological parents (table 1).

Most siblings were biological siblings (87%), 10% had half siblings and 3% step siblings. All but one study (31) are based on convenience samples drawn from schools in the USA, Israel or Italy. In contrast, the UK sample is drawn from a household panel study with 40,000 households and is representative for the whole of the UK (England, Wales, Scotland and Northern Ireland) (31) (see <http://www.understandingsociety.org.uk/>).

PREVALENCE AND TRENDS

Sibling bullying

Three of the studies have information on the prevalence of sibling bullying while the fourth study (30) used a questionnaire (26) to construct scales of sibling or peer victimization and bullying with confirmatory factor analysis. Thus the Italian study does not allow for estimation of prevalence. The US study (29) considered those who answered pretty often/ very often in relevant items of the Peer Relations Questionnaire (adapted for siblings) as involved in bullying. Only 3% were found to be pure victims, most were bully/victims (28.6%) and 14.6% pure bullies (total involvement in sibling bullying: 46.2%) (table 1). The study in Israel (26) counted only those who were frequently victimized (every week or several times a week), i.e., used a more stringent criterion, and did not ask about sibling bullying perpetration. They found that 16.5% were victims with verbal and both verbal and physical bullying (e.g., hitting) most frequent (table 1). The most recent study in the UK considered bullying if it was reported as quite a lot (at least 4 times in the last 6 months) or a lot (at least every week or several times a week). Sixteen percent were pure victims, 33.6% were bully/victims (i.e., were victimized and bullied at other times) and 4.5% were pure bullies (31). Physical bullying (hitting, kicking, pushing) and verbal abuse were the most frequent types of sibling bullying and victimization. No age trend in sibling bullying or victimization was found.

Peer bullying

The rates of peer victimization across the studies were fairly similar with between 12% (31) and 16% (26, 29) of adolescents reporting that they are targets of peer bullying. In contrast, large variation in the prevalence of bullying perpetration were apparent with between 13.1% (26) and 28.4% (29) reported to be bullies (pure bullies or bully/victims) in Israel and the USA but only 1% reporting bullying in the UK (31). Thus very few children admitted to bullying others, a finding replicated in other recent cohorts in the UK (23) (32). It may indicate that efforts to combat bullying in school (33) have resulted in adolescents being less willing to admit to being perpetrators of bullying in schools in the UK. Both the UK and US study looked at age trends and found that peer victimization reduced with age (29, 31).

To summarize, firstly, sibling bullying involvement (as victim or bully) appears to be more frequent with rates as high as 46% to 54%, compared to bullying between peers (29, 31). This is consistent with retrospective reports (27). Secondly, where assessed, most of those involved in sibling bullying are both perpetrators and victims (bully/victims).

In contrast, peer bully/victims are less frequent than pure victims in early adolescence (34). Thirdly, all types of peer victimization reduced with age with older adolescents less likely to become victims of either physical or relational victimization, a finding reported previously (35) (34). In contrast, no changes according to age were found in sibling bullying although this was only investigated systematically in one study (31).

FACTORS ASSOCIATED WITH SIBLING BULLYING

Duncan (29) found that boys were more often victims of sibling bullying but no sex differences in bullying perpetration between the sexes were found. Others found that boys were often sibling bullies or bully/victims while girls were found to be more often pure victims (31). It appears that boys more often bully younger children while females are more often perpetrators of bullying towards older siblings (30).

Overall, younger siblings of older brothers are at increased risk of victimisation (30,31) and may lead to sustained antisocial behaviour towards older siblings (17).

In particular, older brother/younger sister dyads have been found to be characterised by higher levels of conflict and less support (36). Furthermore those with low empathy are more likely to bully their sibling (30). In contrast no relationship of sibling bullying to family type or sibling type (biological or step siblings) was found (31).

BULLIED AT HOME – BULLIED AT SCHOOL?

Arguments that familial and extra-familial relationships are linked come from several theoretical orientations. Social learning theorists have suggested that children learn particular behaviors in relationships with their parents and siblings, and that these behaviors then generalize to their interactions with peers and friends (37) (38). Attachment theory proposes that children's relationships with peers and siblings are influenced by internal working models of relationships which are carried forward from their earliest relationships with attachment figures (39) (40). Another process, which has been suggested as linking familial and extra-familial relationships, is that children's enduring characteristics, such as temperament, elicit similar responses from different relationship partners (41). Each of these theories suggests that there are connections between children's relationships with siblings, friends and peers; however, the proposed mechanisms linking relationships differ according to theory (26).

There is also reason to expect few associations between children's familial and extra-familial relationships. Firstly, siblings growing up in the same context only share, on average, 50% of their segregating genes and they are subject to non-shared experiences in the family and to parental differential treatment (42). Secondly, two children in a friendship or peer relationship are from different families and may have different temperamental characteristics, interests and talents. Their previous experiences in relationships vary and their beliefs and

expectations about how to behave in relationships are likely to differ also. Apart from different characteristics that individuals bring to their relationships, societal norms and culturally held beliefs about how one should behave in particular relationships, such as sibling relationships compared to best friendships, encourage differences and decrease the likelihood of associations between them (43). Associations between children's sibling relationships and their friendships have been reported in several studies, but the pattern of findings is inconsistent. For example, no simple 'carry-over' from sibling relationships to friendships have been found (43).

The four studies reviewed here indicate significant carry-over from sibling victimization to peer victimization. The Israeli study (26) found that of 152 children that were victims at home, 77 (50.7%) were also victims at school, in contrast to only 95 of 769 non-victims at school (12.4%; odds ratio: 7.3; 95% CI: 4.9-10.6). However, this study could not look separately at pure victims versus bully/victims. Duncan (29) found that the majority of peer bully/victims (60%) reported being bullied by their brothers or sisters. Similarly most of peer/bully victims (76.7%) and peer bullies (56.4%) reported that they bully their siblings. The UK study(31) found that victims at home were more likely to be also victims at school (Odds ratio 1.7, 95% CI: 1.3-2.2). However, when the study looked at pure victims and bully/victims separately, the relationship was mainly carried by sibling bully/victims (odds ratio: 1.9; 95% CI: 1.4-2.5) (31).

The Italian study found that sibling victimization was significantly associated with school victimization with standardized path coefficients of .35 to .38 (boys and girls, respectively) after control for a range of individual differences and other sibling relationship factors. Sibling bullying predicted school bullying at a similar level (boys: .30; girls=.35).

All sibling relationships involve conflict occasionally, however, when the conflicts are severe, repetitive and intentional (bullying), then it appears that these have a profound effect on peer relationships. The reviewed studies are all cross-sectional and thus cannot provide evidence for the direction of influence. However, Ensor and colleagues (17) recently reported on an innovative study that combined direct observation of sibling directed antisocial behaviour in the family's homes at 3 and 6 years and interaction of unfamiliar peers in an experimental setting.

The laboratory situation consisted of three unfamiliar children invited to a triadic play situation. Those young children who showed sustained high antisocial behaviour towards their siblings (3 and 6 years) were more likely to bully or refuse to share or interact with unfamiliar peers. Thus, at least in young children, experiences with siblings are predictive of bullying unfamiliar peers.

ASSOCIATIONS OF SIBLING BULLYING WITH BEHAVIOR OR EMOTIONAL PROBLEMS

Original research on potential consequences of peer bullying used cross-sectional studies and found moderate associations with behavioral, emotional or health problems (44-47). Longitudinal studies have now replicated these findings (see Sourander, this issue) (48). Furthermore, the longitudinal research indicates that there may be a dose-effect relationships with those bullied more chronically, severely or experiencing other trauma are at increased risk of adverse outcome (23, 49). Furthermore, initial behavioral or emotional difficulties may both

lead to more likely victimization (48) but victimization itself has a unique adverse effects not accounted for by pre-existing problems or different genetic susceptibility (50).

Three of the four studies of sibling bullying in the literature investigated associations between home and school bullying with behavioral or emotional functioning. The focus will be here on the associations reported with sibling rather than peer bullying.

Firstly, as shown in table 1, the United States (29), Israeli (26) and United Kingdom (31) study all reported relationships between involvement in bullying at home with emotional and behavior problems. This relationship was found even when controlled for bullying experiences in school (26,31).

Secondly, bully/victims whether at home or in school appear at highest risk for maladjustment. The US study (29) found that those who were involved in any sibling bullying and were bully/victims at school were at the highest risk for psychopathology. The Israeli study was large enough to use multiple logistic regression to control for bullying roles in the other context (e.g., sibling bullying controlled for school bullying) and a range of social factors.

Victimization by siblings, being a bully/victim or bully at school was most strongly related to Total and Hyperactivity/Conduct problems (26). Similarly, in the UK study (31), when controlled for bullying experience in school, only being a bully/victim at home was highly significantly associated with clinically relevant total behavior difficulties (Adjusted OR: 3.2 (2.2; 4.7)). Thirdly, all three studies found a clear indication of a dose-effect relationship between sibling and school bullying involvement. While either being bullied at home or school increased maladjustment, being bullied in both settings highly increased the rate of behavior or emotional problems and unhappiness. This is indicated by an interaction between home and school bullying (see table 1).

This effect is illustrated for the UK study of sibling and peer bullying (31) in figure 1 and 2. While victimization at home or school was related to behavior problems or unhappiness, being victimized in both settings led to 10 (figure 2) and 14 times increased odds of unhappiness or clinically relevant behavior problems, respectively.

Finally, a recent longitudinal study examined the short-term stability of bullying victimization at 3 time points over 9 weeks among primary school students in the United Kingdom and Germany (mean age 8.9 years) (32).

The study assessed individual factors, sibling bullying experiences and social network factors in the school classes (e.g., hierarchies, density of relationships, reciprocity etc.) and their contribution to remaining a victim of bullying.

Relative risk analyses indicated a six-fold increased risk of remaining a victim at consequent follow-ups, compared to a child not victimized at baseline becoming a victim over the follow-up period. Individual characteristics explained substantially more variance in the stability of bullying victimization than class-level factors.

Hierarchical logistic regression analyses revealed that being victimized by siblings and being rejected by peers predicted remaining a victim over a nine week period. Overall, being a victim of sibling bullying was the best predictor of remaining a victim at school (OR=2.99; 95% CI = 1.15; 7.77).

Reproduced from Wolke and Skew (31). ** $p < .001$.

¹Odds ratios adjusted in logistic regression for age of adolescents (10-12; 13-15 years), sex, family type (2 categories: natural parents; other), highest parental qualification and family income (in quintiles).

²Abnormal SDQ scores were determined as scores >90th percentile of all adolescents with SDQ data.

¹Odds ratios adjusted in logistic regression for age of adolescents (10-12; 13-15 years), sex, family type (2 natural parents; other), highest parental qualification and family income (in quintiles). ²Unhappy was determined as scores <10th percentile of all Understanding Society adolescents on the Happiness scale.

Figure 2. Relationship between bullying school and unhappiness.

CONCLUSION

Firstly, sibling bullying is widespread and nearly normative with up to 50% involved in bullying every month and between 16%-20% involved in bullying several times a week at home (26, 31). Secondly, being a perpetrator and victim (bully/victim) appears to be the most frequent role taken in sibling bullying involvement. This is in contrast to peer bullying where the most frequent role is victim or bully (21, 35). Thirdly, while victimization and, in particular, bully/victim numbers appear to decrease during adolescence, sibling bullying remains relatively stable over time, at least between 10 and 15 years of age (26, 31). Fourthly, there is consistent evidence that experience of bullying between siblings transfers to peer relationships and bullying involvement in school. Fifth, both bullying siblings at home and between peers at school make unique contributions to explaining behavior and emotional problems. Sibling bullying appears to also predict stability of victimization in school, i.e., those bullied at home are less likely to escape victimization at school (32). Finally, there is a clear dose-effect relationship and their magnitude indicates multiplicative interaction (29)(31). If an adolescent is involved in bullying at home (in particular as a bully/victim) and bullied at school, the odds for emotional and behavior problems are exponentially increased compared to an adolescent just involved in bullying in one context. There is no respite for these school children either at home or at school. Furthermore, experience of parental violence and unpredictability are individual factors relevant to severe sibling violence (2). These children are poly victimized (51).

There are a number of limitations concerning this review. All, but the study of victimization stability (32), are cross-sectional analyses and do not allow for conclusions regarding causality: Are children with behavior problems more often bullied or does bullying lead to behavior or emotional problems and less wellbeing? It may be that both mechanisms, as shown for school bullying, may be operating (48) and that siblings with certain temperamental characteristics may elicit bullying (2) (52). Longitudinal research in large enough samples is required to help disentangle whether sibling bullying uniquely contributes to less wellbeing and maladjustment. Furthermore, report by other data sources and linkage to other data including school examination results and health data could provide objective measures of outcomes that do not rely on self-report. To understand mechanisms it will be necessary to investigate family constellations (53) (54), and assess other members of the household (2). It appears that combinations of an older brother and younger sister may be a particular recipe for conflict (30).

Despite these limitations, the findings so far are compelling enough to suggest that for those victimized at home and at school there is little escape from bullying and its consequences. Sibling relationships appear to be a training ground with implications for wellbeing of the individual (25). Previously trans-context effects from home to peer relationships and wellbeing have been reported for highly positive sibling relationships (11) – this review extends this by showing that highly negative sibling relations also transfer across contexts. Overall, bullying is one of the major safety concerns for parents as also reported by the recent UK Staying Safe Survey in the UK (55) that interviewed young people aged 12 to 17, and parents/carers. Bullying was the second highest concern expressed about children's safety by parents (61%), and also by children (though only by 35%). The current findings add that bullying also takes place at home, starts very early in life (17), is related to parenting (2) and interventions should include the family and parenting skills of dealing with repeated conflicts between siblings.

Bullying starts at home! Strengthening families and parenting skills and increasing sibling support is likely to reduce bullying in school and increase wellbeing (13).

Chapter 75

BULLYING: A STEPPING STONE TO DATING AGGRESSION?

Wendy L. Josephson*, PhD and Debra Pepler, PhD

Department of Psychology, University of Winnipeg, Winnipeg
York University and the Hospital for Sick Children, Toronto, Canada

ABSTRACT

Bullying is the use of power and aggression to control and distress another. In this chapter, we review research to explore whether the lessons learned in bullying provide a stepping stone to aggressive behavior in dating relationships. We start by considering definitions and a relationship framework with which to understand both bullying and dating aggression. We consider bullying from a developmental-contextual perspective and consider risk factors associated with the typical developmental patterns for bullying and dating aggression, including developmental and sociodemographic, individual attributes, and family, peer group, community, and societal relationship contexts that might lead some children and youths to follow developmental pathways that lead to bullying and dating aggression. We conclude by discussing implications for intervention with a review of evidence-based interventions.

INTRODUCTION

Bullying is the use of power and aggression to control and distress another. We are concerned that the lessons learned in bullying may provide a stepping stone to aggressive behavior in dating relationships and lay the foundation for troubled relationships across the lifespan. Although there is research linking experiences of victimization within dating relationships to victimization in other kinds of relationships (1-4), we have limited our focus in this review to the development of children and youth who bully, and adolescents who perpetrate dating aggression.

* Corresponding Author's Email: w.josephson@uwinnipeg.ca.

For this chapter, we reviewed research on the link between bullying and dating aggression by conducting a literature search with Scholars Portal (February 2011). There were 634 publications identified with the keywords ‘dating violence’ or ‘dating aggression’. When we narrowed the search to include ‘bullying’, there were only 21 articles, dating back to 2001, in which the keywords bullying and dating violence or aggression were both used. Most did not explicitly investigate whether the two are linked. From the outset, then, it was clear that the empirical literature bearing directly on this question is sparse. Nonetheless, we believe there is a case to be made for such a link, and we attempt to draw together the evidence to support this hypothesized link between bullying and dating aggression. We start by considering definitions and a relationship framework with which to understand both bullying and dating aggression, followed by a consideration of a theoretical perspective and empirical data on the prevalence and commonalities in individual and relationship risk factors associated with bullying and dating aggression. We conclude by discussing implications for intervention in light of evidence-based interventions.

BACKGROUND

Bullying is a form of repeated interpersonal aggression in which there is a power differential between the individual who is bullying and the individual being victimized (5). Bullying can be direct, such as physical and verbal bullying, or indirect, such as social exclusion or malicious gossip; it may be conducted face-to-face or electronically (6). Our research over the past 20 years has helped us understand bullying as a relationship problem that requires relationship solutions (7). The issue of power within relationships is central to bullying. The power of those who bully comes from recognizing and targeting others’ vulnerabilities related to factors such as age, race, gender, sexual orientation, disability, difference, or disadvantage. When children and youths are repeatedly involved in bullying their peers, they experience regular lessons in the use of power and aggression to control and distress others. In many ways, youths who bully are reinforced for their aggression: they gain power over the victimized child, they receive the attention of peers (8), and gain status in the peer group (9). Conversely, children and youths who are repeatedly victimized become trapped in a destructive relationship in which they become increasingly powerless and unable to defend themselves. A small proportion of children, who are generally the most troubled, are involved in both bullying their peers and being victimized by their peers (10).

The nature of bullying changes through the elementary, middle, and high school years. Bullying can start in early childhood and persist through the school years, peaking during the school transition (11). The use of coercive power and aggression in relationships generally drops off as children and youth learn that this is an ineffective means of maintaining relationships. A small proportion of youths, however, persist in their frequent use of coercive power and aggression through adolescence and into high school (12).

Other youths engage in intermittent bullying throughout the school years, perhaps to selectively assert power over individuals and within the peer group. As with other forms of problem behavior, it is important to recognize the heterogeneity in the developmental of bullying as this has implications for prevention and intervention.

DEFINITION OF DATING AGGRESSION

Dating aggression is actual or threatened harm by one partner in a dating relationship against the other partner (13). Physical aggression may include slapping, scratching, pushing, and shoving, as well as more severe behaviors such as biting, choking, shaking, punching, burning, or use of a weapon. Psychological aggression includes verbal or coercive behaviors that deliberately control, embarrass, humiliate, or isolate the dating partner from friends or family. Both physical and psychological dating aggression may be sexual in nature – such as forcing a dating partner to engage in an unwanted sexual act, or sexual humiliation. Among adolescents, dating aggression tends to be mutual: if one partner is aggressive, the other typically retaliates (14).

BULLYING AS A PRECURSOR TO OTHER RELATIONSHIP PROBLEMS

Just as not all peer aggression meets the criteria we use to define bullying, it is likely that not all dating aggression is part of a pattern of bullying. The most common version of dating aggression is relatively infrequent and not usually part of a systematic attempt to exert power over the dating partner (15). Bullying, however, is a risk factor for dating aggression (11), which in turn is a risk factor for adult intimate partner violence (16). Moreover, when dating aggression is systematic, recurrent, one-sided, and based on power motivation (i.e., shares the defining elements of bullying), it is much more similar to the type of intimate partner violence that Kelly and Johnson (15) have called Coercive Controlling Violence, and Carlson and Jones (17) have identified as the most severe and dangerous. Within our research program, we have hypothesized that the interactional style that characterizes bullying within the peer group (the use of aggression and other forms of coercion to exert power over another) may transfer to the context of romantic relationships. We have long believed that the use of power and aggression in bullying may foreshadow their later use to control and distress the other person in a multitude of later relationships, in forms such as sexual harassment, dating violence, gang violence, marital violence, child abuse, workplace harassment and elder abuse ((18); also see Corvo & deLara (19) who have also suggested such a pathway).

THEORETICAL PERSPECTIVE

We have adopted a developmental-contextual perspective (20,21), which treats development as a continuous and cumulative process influenced by the ongoing series of mutual transactions between individuals and the physical, social and cultural contexts in which they are developing. The nature and outcome of those transactions is affected by factors associated with both the individuals and the various layers of their contexts, with different aspects of each becoming important or salient at different points in the developmental process. Children will not all develop in the same way because of their unique individual qualities and the different environments in which they are interacting; environments will respond differently to children who have different qualities, and change because of children's influence on them.

Table 1. Risk Factors for Bullying and Dating Aggression

	Bullying	Dating Aggression
Developmental and Socio-Demographic Characteristics		
Age	Bullying increases across elementary school, peaking at the school transition, and decreases through high school (11,22)	Physical and sexual dating aggression increase with age up to about age 16 or 17 (23) then decrease (23,24) Psychological and relational aggression increase with age (23,25)
Gender	Boys report higher rates of bullying than girls across age (26) Boys engage in more physical bullying than girls (8) Girls and boys are similar in rates of verbal and cyber bullying (27)	Boys more likely to perpetrate severe dating abuse (23) and sexual dating abuse(23,28,29) Girls more likely to perpetrate relational (25) and physical dating aggression (24,27,29) but desist more rapidly in late adolescence (24)
Ethnic and cultural background	Few differences in the rates of bullying by youths of varying races (31). Different rates of bullying perpetration by race linked to youths reporting being bullied because of their race (32)	Minority status individuals more likely to perpetrate dating aggression (23,33,34) Adolescents of Asian heritage less likely to engage in dating violence than other ethnic groups (30)
Other Individual Attributes	Early pubertal development (35) Depressive symptoms (36) Moral disengagement (12, 37)	Early pubertal development (11) Depression (34,38) Chronic anger (25,34) Chronic anxiety (25,34,38) Lack of reasoning-based conflict resolution skills (39) Low self control or self regulation (25,40,41) Hostile attribution bias (42) Rejection sensitivity (43,44) Relationship insecurity (44)
Individual		
Attitudes & Beliefs	Attitudes condoning bullying (45,46)	Attitudes condoning dating aggression(28,33,39,47,48,49) Positive attitudes toward traditional gender roles (28) Gender stereotypes (33) Low perceived penalties for dating aggression (33)
Behaviors	Delinquency (50) Alcohol use (51) Drug use (51) Physical aggression (12) Social aggression (12) Rule breaking (52)	Delinquency (38,47,53) Alcohol use (51) Drug use (34,51,53) Aggression against peers (25,34) Verbal aggression, blaming, conflict escalation (39) Bullying of peers (11,35,38) Sexual harassment of same- sex and cross-sex peers (11,35) Aggression against parents (54) Aggression against previous romantic partners (47)

	Bullying	Dating Aggression
Relationship Context		
Family	More conflict and less trust with their parents (12) Harsh physical punishment (55,56) Low parental monitoring (12) Low levels of warmth and cohesion (57) Not living with both parents (12)	Family conflict (40) Childhood victimization by parents (28,38, 42, 54) Harsh parenting (53,54) Parents' psychological violence (excessive harshness + parental disorganization) (38) Low parental monitoring (25,53) Psychologically controlling parenting by mother (25) Witnessing parents' relationship violence (33) Single parent household (23,33,38) SES (parents' education) (23,24)
Peers	Having friends who bully (12) High conflict with friends (12) Susceptibility to peer pressure to engage in deviant behavior (12) Increased peer status (58)	Having friends who aggress against dating partners (28,34,40) Having friends who express norms supporting dating aggression (40) Victimization by peers (47)
Romantic Dyad	Early into romantic relationships (35) Physical aggression in dating relationships (51)	High level of conflict with romantic partner (47) Jealousy and controlling behavior toward romantic partner (13) Hostile couple interactions (33,39,47,48,59) Power imbalance (60) Partner's dating aggression (4,13,24,28,29,30,47,49)
School/ community	Levels of violence in the school neighbourhood were related to higher levels of bullying at school (61) Poor relationships with their teachers (62)	Exposure to community violence predicted dating aggression (63)
Societal	Income inequity at national level linked to levels of bullying (64,65)	Aggressive media use (48)

It is our contention that relationships are the key to understanding these transactions at every developmental phase and in every contextual domain. We have employed this perspective in the organization of Table 1, which presents empirically-established risk factors for both bullying and dating aggression. We begin Table 1 with the developmental and socio-demographic risk factors associated with the typical developmental patterns for bullying and dating aggression. We next identify individual attributes in Table 1 that might lead some individuals to be more likely than others to follow developmental pathways that lead to bullying and dating aggression, and finally examine the contexts in which development occurs: the family, peer group, community, and broader society.

RISK FACTORS RELATED TO BULLYING AND DATING AGGRESSION

Bullying

In our cross-sectional research (11), we found that the rates of bullying were highest around the transition from elementary to high school and were lowest at the end of high school. Longitudinal analyses revealed that there is substantial variability in the development of bullying, with four common pathways from ages 10 to 17 (12). One group (10%) reported consistently high levels of bullying from late elementary through high school. A second group (13%) reported similarly high levels of bullying in elementary school, but by the end of high school they reported that they almost never bullied their peers. A third group (35%) reported moderate levels of bullying across these years. The final group (42%) reported very low levels of bullying from age 10 to 17. There were more boys represented in the chronically high bullying group and more girls represented in the group with low levels of bullying. The nature of bullying changes with age. Rates of physical bullying peak in Grade 8 and then decline (66). From late childhood, new forms of bullying emerge. With developing cognitive and social skills, children become aware of others' vulnerabilities and of their power relative to others. Bullying then diversifies into more sophisticated forms of verbal, social, and electronic bullying, as well as sexual harassment and dating aggression (11). Boys tend to engage in physical forms of bullying and sexual harassment more than girls (67). Girls and boys exhibit similar levels of electronic, verbal, and social bullying (66). There are generally few differences in the rates of bullying by youths of varying races (31). When there are racial differences in rates of bullying perpetration, the youth who report bullying their peers also tend to report being bullied because of their race (32).

Dating aggression

The most common trajectory of psychological and relational dating aggression is for these behaviors to increase with age throughout adolescence. Physical and sexual dating aggression typically increase up to about age 16 or 17, then decrease, presumably reflecting a greater social sophistication and recognition that aggression is an ineffective problem-solving strategy. Girls use more relational dating aggression than boys do. They also have higher rates of physical dating aggression than boys do, perhaps reflecting the greater social acceptance typically reported for aggression by girls against boys (28,39). Boys are more likely to report using severe forms of dating abuse (such as choking or beating up), and sexual dating aggression (23,28,29). Girls tend to desist in their use of dating aggression more rapidly than boys do with age (24). Minority group status, accompanied as it typically is by prejudice, exclusion, and material hardship, is frequently associated with higher rates of dating aggression, but some minority culture groups (such as Asian-Americans (30)) may have values and customs that serve as a protective factor against the development of dating aggression.

INDIVIDUAL RISK FACTORS

Bullying

Children and youth who persistently bully have a range of individual problems. They have a tendency to be generally aggressive in their peer relationships – they engage in more physical and social aggression than their non-bullying peers (12). These youth may not have acquired the essential behavioral and emotional self regulation and social skills required for healthy relationships. The youth who bully at a high and moderate rate are also more morally disengaged than those children who do not bully. Bandura (68) described moral disengagement as a lack of self-regulation regarding moral conduct. These children ignore the critical message that bullying is wrong and hurtful. They consistently report being mean and cruel to others, not being trustworthy, being manipulative, and lacking guilt. It is important to keep in mind the heterogeneity among children and youth who bully their peers. On an individual case basis, it is important to determine whether a child is being aggressive and not attending to the feelings and well-being of others because he/she is dysregulated and not able to perspective take or whether he/she chooses not to take into account the harm to others because of the social advantages achieved through bullying. In general, youth who bully tend to have a range of mental health problems, which may be related to their lack of behavioral and emotional self regulation. As might be expected, youth who bully their peers experience more externalizing problems such as aggression and delinquency and antisocial personality symptoms (69,70). They also engage in higher levels of alcohol and other substance use starting at an early age (51). Consistent with these problems, youths who bully experience a range of school achievement problems (52). Some youths who bully also report elevated levels of depressive symptoms (36), as well as physical complaints, such as headaches (71).

Dating aggression

Adolescents who engage in dating aggression, or use it increasingly with time while their peers desist, have a disproportionate tendency to be depressed, chronically angry or anxious (25,34,38), insecure about their relationships, and excessively sensitive to rejection (43,44). They are likely to interpret ambiguous social cues as signaling rejection or threat (42). They lack competence in regulating their emotions and behavior (25,40,41), and have not developed the skills they need to interact effectively with their peers and resolve interpersonal conflict constructively (39). Early pubertal development is an additional risk factor, perhaps because the hormonal and physical changes of puberty are harder to cope with effectively at a younger age. Recent research by Ellis and his colleagues (72) suggests that early pubertal development may be a marker for an interaction between an aspect of the family context and an individual's biological sensitivity to the environment: They found that early and fast-paced pubertal development was associated with the combination of high stress reactivity and low quality parent-child relationships. Adolescents who engage in dating aggression have a belief system that supports that behavior: They have generally accepting attitudes about dating aggression, traditional or stereotypical ideas about gender, and expect that there will be few negative consequences for aggression against a dating partner (33, 39, 47-49,60). Similar to bullying, dating aggression is associated with a host of risky and problematic behaviors, including other forms of aggression against peers, aggression against parents, sexual harassment, delinquency, and the use of alcohol and other drugs. In the specific domain of dating relationships, it is

associated with a verbally aggressive, blaming and escalating style of dealing with conflict, and with jealous, controlling behavior toward the romantic partner. Aggression in one dating relationship increases the probability that it will occur in subsequent dating relationships.

Relationship risk factors

Although the relationship contexts shift significantly from childhood into adolescence, the risks associated with troubled relationships are related to both bullying in childhood and dating aggression in adolescence. As they mature, adolescents are faced with the task of developing their identity and, at the same time, they develop increased autonomy from their parents and sometimes experience more strain in their relationships with parents. As they distance themselves from parents, adolescents become closer to both same-sex and opposite-sex friends, and begin the process of developing intimate relationships.

FAMILY RELATIONSHIPS

Bullying

Children and youth who bully others are more likely than non-bullying youth to come from families characterized by low levels of family warmth and cohesion (57). In mid-adolescence, youths with a history of frequently bullying others report significantly more conflict with their parents and significantly less trust in their parents (i.e., not feeling that their parents would be there for them when they needed them) compared to youths who do not bully. Adolescents with a history of moderate bullying also report significantly less trust in their parents than adolescents who do not bully (12).

Adolescents whose parents are authoritarian and use physical punishment are more likely to bully others than adolescents who are not physically punished (55, 56). Exposure to models of interpersonal aggression through interparental violence predicts bullying above and beyond children's direct experiences of maltreatment (55).

In addition, children and youth who bully others are more likely than non-bullying youth to report that they have poor communication with their parents and that their parents are poor in monitoring their activities (12), which often reflects willingness of adolescents to disclose to their parents (73).

Dating aggression

Adolescents who engage in dating aggression are likely to have been raised in families under strain – lacking educational and other resources, shouldering the responsibilities of raising children as single parents (23,33), and/or having high conflict (40). Youth who engage in dating aggression tend to have experienced maltreatment, themselves (28, 54) and witnessed marital violence (33). Parents in these strained families sometimes respond to their situations by being harshly punitive, psychologically controlling, and even abusive to their children. In

such households, children's relationships with their parents do not provide them with the models and support they need to accomplish the important developmental task of developing the capacity for relationships. This contributes to or exacerbates the individual vulnerabilities that we have just discussed above, leading to the children becoming even more of a challenge to their parents and further undermining their parents' effectiveness (74). When these youth enter adolescence, struggling parents may also fail to provide the support they need to make the transition into more complex and intimate relationships.

PEER RELATIONSHIPS

Bullying

Bullying unfolds in the context of the peer group almost all of the time (8). Children and youths who chronically bully their peers may be trying to establish a place for themselves in the peer group. They use bullying to establish status and power over others and, in the process, are often at the center of attention within the peer group (8, 58, 75). In some respects, bullying may be a bid for inclusion, leadership, and status, albeit a negative one. We have found that boys and girls who bully have an ambivalent friendship profile (26). For example, in early adolescence, they report spending more time in activities with peers than other youths, suggesting they are well integrated into a peer group. These friendships, however, may be problematic.

These same youths report more conflict in their friendships than youths who do not bully. These adolescents may not have developed the diverse social competencies and positive conflict resolution strategies that are required for mature, balanced friendships. Although the negative leadership style of youths who persistently bully may enable them to maintain peer contacts and develop some form of peer status, it appears to create challenging relationship contexts that may serve to sustain antisocial behavior patterns through and beyond adolescence.

Children and adolescents who persistently bully at a high or moderate rate have high conflict in their peer relationships, choose friends who also engage in bullying and they are highly susceptible to negative peer pressure from their friends (12). In this peer context, bullying is likely to become a more firmly established pattern of behavior. When peers also victimize these troubled youth, and act as role models by being aggressive in their own dating relationships, these peer associations become a risk factor for dating aggression.

Dating aggression

Dating aggression is most common in romantic relationships that have a high level of conflict (47), in which the partners tend to interact in an irritable, hostile, disrespectful and conflict-escalating way (33,39,48,59), and in which there is an imbalance of power between the partners (60). Aggression by an individual's dating partner is one of the strongest predictors of that individual's own aggression (4, 13, 24, 28, 29, 30, 47, 49).

RISK FACTORS WITHIN THE COMMUNITY AND BROADER SOCIETY

Bullying

The most important social context for children beyond the family is the school community. Consistent with the other contextual risks, troubled relationships within the school context are associated with a higher risk for bullying. Children who bully their peers tend to have poor relationships with their teachers, including little or no mutual warmth, caring, or generally positive feelings (62). Conversely, there is a reliable association between a positive school climate (i.e., warm relationships and consistently applied high standards for behavior) and low levels of bullying and aggression in schools (76, 77).

In a nation-wide study in Colombia, Chaux and colleagues (61) found that many school-level factors are associated with higher levels of bullying including: low empathy, beliefs supporting aggression, hostile attributional biases, and poor anger management. They also found that levels of violence in the school neighborhood were related to higher levels of bullying at school.

At a broader societal level, there is emerging evidence of a strong association between the level of income inequity for a municipality (61) and for a country (64) and the level of bullying and other forms of interpersonal aggression among youth. From analyses of income inequity in the developed world, Wilkinson and Pickett (65) contend that the process of social comparison and a drive to have status underlie many interpersonal and health problems.

Dating aggression

There is some evidence that dating aggression is higher among adolescents who have been directly exposed to violence in their community (63). In addition, exposure to media appears to have an influence on dating aggression. Adolescents who regularly consume aggressive television, movies, video games and music have higher rates of dating aggression, and this relationship is mediated by increased acceptance of dating aggression (60). Considerably more research is required in this area of concern.

IS BULLYING A STEPPING STONE TO DATING AGGRESSION?

If dating relationships provide a context in which youth can continue to express and establish interpersonal power and dominance through aggression, then interactions in these intimate adolescent relationships may lay the foundation for later relationship violence in adulthood. One of the most striking observations about our review of the risk factors in Table 1 is how similar the profiles of risk factors are for bullying and dating aggression. A longitudinal study by Fergusson, Boden and Horwood (78) suggests that the predictors of intimate partner violence in adulthood are very similar as well. Although having common risk factors does not necessarily mean that these aggressive interactional styles are progressive steps on a common developmental path, it is consistent with that hypothesis.

In addition, our research (11,35) and that of others (38) have revealed that young adolescents who perpetrate bullying become involved in romantic relationships earlier than those who do not bully, and are more likely to report verbal and physical aggression in their earliest intimate relationships.

It is logical, especially from a developmental-contextual perspective, to expect that the lessons learned in one relationship domain will transfer to new relationships as these develop. This hypothesis is consistent with attachment theory in which it is argued that the earliest relationship between children and their parents provides an internal working model of relationships that children use for developing other relationships through childhood and adolescence (79). In line with attachment theory, Furman and colleagues (80) found that adolescents' working models and relational styles for dating relationships had a close resemblance to those for friendships on the dimension of control in the relationship, even though they had a stronger resemblance to parent-child relationships on the dimension of support. Although we do not yet have convincing longitudinal evidence about the specific path between bullying and dating aggression, the evidence is growing about the transfer of aggression between other relationship domains. For instance, we have found in a longitudinal study (47) that dating aggression predicts later aggression in a different dating relationship.

We have also found (54) that adolescent aggression against parents remains strongly related to dating aggression even after partialling out the shared variance associated with age, family income, dating victimization, and childhood victimization.

More directly to our point, Pettit et al. (81) found that experiences in the peer relationship domain are powerful influences on later behavior in the romantic relationship domain. In a longitudinal study of rejection in parent, peer and romantic relationships, they found that biases in social information processes about peers and romantic partners were so closely related that separate paths for peer and dating experiences were not empirically justified.

Fredland (82) has suggested that there is a transitional stage between bullying and dating violence in which the form and content of bullying begins to reflect the sexual interest and preoccupations associated with puberty. Guerra, Williams & Sadek (83) collected qualitative data that support that contention. Youths in their focus groups expressed a common theme that bullying in middle school often grew out of sexual or romantic attraction, and took on a noticeably sexual tenor.

This is consistent with our quantitative findings (21) that cross-gender (and not same-gender) harassment increased in frequency from Grade 6 to Grade 8, and was linked to pubertal maturation and participation in mixed-gender peer groups. It is also consistent with Pelligrini's (22) finding of a relationship between bullying at the beginning of seventh grade and sexual harassment at the end of that grade, fully mediated by students' dating frequency.

Considerably more research is required to understand the complex developmental processes that may underlie the links between bullying and dating aggression. Understanding bullying as a relationship problem highlights that these patterns of interpersonal aggression in childhood and adolescence arise from complex transactional dynamics rather than simply from an individual child's problem with aggression or with another child's inability to defend him or herself. Relationships are "active ingredients" of the environment's influence on healthy development (84). It is important, therefore, to consider how daily interactions at home, school, and in the community shape children's development of critical social, emotional, behavioral, and cognitive capacities. Unlike lessons in reading and arithmetic, with step-by-step processes that enable most children to acquire the skills, the lessons for successful social interactions are

much more complex and not fully understood. They require developing an understanding of one's own thoughts, emotions, and behaviors, as well as the thoughts, emotions, and behaviors of others. Those with whom children interact are highly variable and often unpredictable: even a single person varies from day to day in warmth, responsiveness, and emotions. The complexity of social interactions highlights the need to provide extensive, dynamic, and ongoing socialization support to children to enable them to relate positively to others, be effective in achieving social goals, and use their interpersonal power positively, rather than negatively.

In the following section, we briefly review prevention and intervention strategies to support the development of relationship capacity and prevent interpersonal aggression through childhood and adolescence.

PREVENTION, EARLY IDENTIFICATION AND INTERVENTION

Foshee and Reyes (85) have made a number of valuable recommendations about how primary prevention of dating aggression should be done for adolescents, to whom they should be directed, and when they should be introduced. We are in essential agreement with their suggestions, but would extend them somewhat further with a consideration of bullying as a potential stepping stone to dating aggression and by offering some suggestions about what content areas are most likely to be important.

HOW SHOULD PREVENTION AND INTERVENTION BE DONE?

Based on their review of longitudinal predictors of dating aggression, Foshee and Reyes (85) identified three areas on which they thought prevention efforts should focus: Improved parenting; prevention of behavioral precursors to dating aggression, such as peer aggression, delinquency, alcohol and substance use; and changing peer contexts to be less supportive of dating aggression. This is very consistent with our assessment of risk factors for both bullying and dating aggression, and the developmental-contextual perspective we have adopted. Among the many behavioral precursors to dating aggression, we would particularly emphasize the importance of an interactional style developed through persistent bullying. With respect to the content of bullying and dating aggression prevention programs, we recommend the following program features:

- *Focus on relationships.* Regardless of the developmental stage at which prevention or intervention efforts occur, bullying and dating aggression are problems with relationships and must be addressed with relationship solutions. Our research and our review of others' research have convinced us that the best way to deal with these problems is to help young people develop positive, supportive relationships, highlighting the skills and social cognitions that are essential for healthy relationships before and through the time that romantic relationships are beginning to form. The Fourth R is a curriculum-based program that addresses adolescent risk behaviors by focusing on relationship goals and challenges that influence youths decision-making.

In a rigorous evaluation of the program, Wolfe and his colleagues (86) confirmed that teaching youth about healthy relationships and ways to avoid physical dating violence in Grade 9 Health classes can reduce physical dating violence and related risk behaviors 2.5 years later, especially for boys.

- *Emphasis on skill-building.* In their focus group study of dating aggression, Sears and her colleagues (28) found that high school students very much wanted help to develop skills for maintaining healthy dating relationships and dealing with relationship conflict. Therefore, prevention efforts may find a receptive audience if they provide an opportunity for children and adolescents to build strong relationship skills. Safe Dates (87) and the Youth Relationships Project (88) are evidence-based dating aggression prevention programs that provide compelling empirical evidence of reducing physical dating aggression (85,89). These programs include extensive role playing activities to help young people learn communication and conflict management skills. Similar skill-building elements are found in bullying prevention programs. For example, the Finnish KiVa program (90) includes instruction and role play to build skills in supporting peers who are being bullied, and has been shown to be effective in reducing bullying.
- *Focus on peer contexts.* Like Foshee and Reyes (85), we think that the peer context is critical to changing children and adolescents' relationship behaviors. KiVa (for bullying) and Safe Dates (for dating aggression) reduce bullying and dating aggression by changing the way in which peers respond to them. Evaluation of the Safe Dates program (91) confirmed that changes to social norms in the peer group were significant mediators of reduced dating aggression.
- *A comprehensive approach.* Our developmental-contextual perspective leads us to agree with Foshee and Reyes that prevention efforts will be more effective if they affect multiple layers of the context in which young people are embedded. The Olweus Bullying Prevention Program, an evidence-based bullying prevention program, includes components at the individual, peer group, school, and community levels (92). Safe Dates addresses the peer layer especially, but also introduces resources from the surrounding community; awareness of community services was also a mediator of the program's beneficial effects (91). Given the demonstrated associations between family factors and the development of bullying and dating aggression, we would recommend an increased opportunity for parents to learn about promoting healthy relationships for their children. An example of supporting parents to support their youth can be found in the Connect® program developed by Moretti and her colleagues (93). In this program, parents of troubled youth are taught to: 1. Identify relationship and developmental issues related to problem behavior and conflict; 2. Step back and consider parenting choices that maintain emotional availability even in situations of conflict; 3. Understand and manage their own emotional reactions to conflict with their teen, and 4. Use basic parenting skills to support their relationship with their teen while setting limits. Preliminary evaluations are indicating both short and long term improvements for both troubled youth and their parents. Beyond parents, we believe that all adults involved with children and youth need the skills and understanding to promote healthy relationships. In our national Promoting Relationships and Eliminating Violence Network (PREVNet), we are working with more than 50

national organizations to enhance the practice of adults involved with children and youth across Canada (94).

- *Focus on the issue of power.* A major thesis in this paper is that bullying is a gateway or stepping stone to dating aggression because bullying teaches children to use power coercively to control vulnerable others. An intervention that prevents this pattern, or reverses it, will need to deal explicitly with the issue of interpersonal power, and help young people learn to use power in a way that is positive, respectful, and shared. The Youth Relationships Project (88) includes extensive opportunities for participants to discuss and practice the positive use of power.

WHEN SHOULD PREVENTION AND INTERVENTION BE DONE?

Foshee and Reyes (85) have pointed out that the best timing for prevention of dating aggression is in the short window during which dating is developmentally relevant to young people, but before patterns of aggression have time to develop in dating relationships. They recommend that prevention programs begin at about age 13 (eighth grade) in order to take advantage of this opportunity.

As they noted, many young people will have begun some variant of dating by that time, and our research (51) indicates that those who have begun dating by that time are disproportionately at risk to be involved in both bullying and dating aggression. Although we agree that the eighth grade is a good time to begin programs that specifically deal with dating aggression, a developmental pathway from bullying to dating aggression implies that efforts to prevent or intervene with bullying behavior, which could begin much earlier, would contribute to the prevention of dating aggression, regardless of when dating begins. It would also be important to make a concerted effort to prevent and intervene in sexual bullying, which appears to increase just prior to initial dating, beginning at around sixth grade.

TO WHOM SHOULD PREVENTION AND INTERVENTION BE PROVIDED?

Foshee and Reyes (85) have pointed out that there are advantages and disadvantages to both universal and more targeted (selected or indicated) prevention efforts. Our understanding of the diversity in developmental pathways for both bullying and dating aggression and the review of the risk factors have convinced us that both are necessary. Universal programs can promote early prevention and provide the necessary changes in the relationships that promote social-emotional development in the family, peer group, school, or community contexts. For those children and youth who are especially at risk, targeted programs can be used to address the individual and relationship risk factors and enhance protective factors to promote healthy social-emotional development. The Olweus Bullying Prevention Program and KiVa both have universal components but intense interventions with those who are found to be directly involved as perpetrators or victims of bullying. The Youth Relationships Project is offered to high risk youth who have been maltreated or who have witnessed domestic violence, as referred from social service or victim protection agencies, but has been run in tandem with the universal Fourth R program (95,96).

CONCLUSION

Healthy relationships are the foundation for children's and adolescents' development and the cornerstone for a healthy and productive society. Children can only develop the capacity for healthy relationships if they grow up within safe and healthy relationship contexts. The United Nations Convention on the Rights of the Child (97) provides an international policy and legal framework for ensuring the rights of the child for safety and many other critical elements for healthy development.

The Kandersteg Declaration (98) recommends action to use policy and prevention programs which are: based on scientific research; appropriate for age, gender, and culture; and multi-systemic involving families, peers, schools, and communities. It also recommends action to evaluate the success of policy and programs and to guarantee the rights of children and youth. At this point, there is a substantial gap between these calls and requirements and the lived experiences of children and youth in their families, schools, peer groups and communities. We are particularly concerned for those children and youth who are learning to use aggression within peer and dating relationships, as well as for those youths who are on the receiving end of this aggression.

As researchers, we believe we have an important role in closing the gap between what is envisioned for the healthy development of children and youth and what currently exists to promote their safe and respectful relationships and full potential.

By preventing violence and promoting healthy relationships for children and adolescents, we can optimize their healthy physical, social, emotional, and cognitive development – all of which underlie well-being, healthy relationships, productivity, and citizenship throughout the lifespan.

Chapter 76

WORKPLACE BULLYING: THE CASE OF TEEN WORKERS

Loraleigh Keashly*, PhD

Department of Communication, Wayne State University, Detroit, Michigan, US

ABSTRACT

Work is an important yet understudied life domain for adolescents that has important implications for their development and well-being. Work relationships, particularly with supervisors and coworkers are critical influences on teens. To the extent these relationships are negative, as evidenced in workplace bullying, the impact on teens can be wide-ranging and enduring. In this chapter, research on workplace bullying and its effects is briefly summarized and used as a context for exploring adolescent experiences with bullying on the job, both in terms of their vulnerability to exposure and unique impacts. Implications of these findings for health professionals in the assessment and treatment of teens exposed to workplace bullying are discussed.

INTRODUCTION

Work is a part of many adolescents' daily lives. According to the International Labor Organization (ILO), in 2009, youth (15-24 years old) are a notable part of the working world with rates varying from 24% of youth in Hungary to close to 79% in Uganda (1). In North America, the majority of young people are engaged in some form of paid employment (United States 56.3% and Canada 68.4%). The US Bureau of Labor's National Longitudinal Survey of Youth 1997 found that working while attending high school increased with age ranging from 41% for freshman (13-14 year olds) to 87% of seniors (17-19 yr olds) with a notable portion of these students working 21 hr or more per week (e.g., 25% of working freshman and 56% of working seniors) rivaling their in-class school time (2). By far the majority of youth workers are nonstandard employees (i.e., part-time or temporary), often a result of also being in school.

* Corresponding Author's Email: l.keashly@wayne.edu.

According to U.S. statistics, the majority of adolescents work in unskilled entry-level jobs, most frequently in eating and drinking establishments (33%) and other service industries such as custodial and construction work (25%) (2). Given that teens work, examining the nature and connection of working generally, and specific work experiences in particular to adolescent health and well-being is important.

RELEVANCE OF WORK FOR ADOLESCENTS

Work is a critical life domain for anyone but it may be particularly powerful for adolescents. Beyond the provision of economic benefits, work is a source of identity, psychological health, and provides opportunities for interpersonal connection and self-determination (3). Work has a special relevance for adolescents as it represents an initial foray into a “domain that will be central to their adaptation and social standing as adults” (4, pg. 546). Working can support developing autonomy and independence that are key tasks for adolescents. Within this context, adolescents may learn not only skills and knowledge relevant to particular types of work but also attitudes and behaviors that will be relevant to future occupational achievement. Further, work experiences “spillover” and thus have implications for other life domains such as family, friends, and for many adolescents, school (5, 6, 7). Work also provides adolescents with interaction with adults other than teachers and parents who can mentor and provide alternative role models (4). Finally, and perhaps most importantly, early work experiences have implications for overall identity development.

Skorikov and Vondracek argue that vocational identity is the driving force behind identity development (8). Thus, what happens “on the job” has implications for adolescents’ sense of efficacy and confidence about who they are and their abilities to be successful as adults.

IMPORTANCE OF WORK RELATIONSHIPS

Of particular relevance to this discussion of workplace bullying is the recognition that the nature of work is inherently relational. What is accomplished at work is done in and through interactions with others. Quality of interpersonal work relationships has been identified as a powerful influence on workers’ mental and physical health (9). Interpersonal relationships are critical in most jobs as people interact with coworkers, supervisors, subordinates and customers and this social context gives work its meaning. These relationships can buffer or exacerbate adverse effects of exposure to job risk factors (10). Indeed, these relationships can become the source of stress and harm as evidenced by the workplace harassment, bullying and aggression literatures (11, 12).

In addition to their immediate impact, interpersonal work experiences may have influence beyond the immediate interaction. Such experiences may become internalized and influence how an individual views and reacts to interpersonal interactions and other life experiences across diverse contexts (3). Further, it is through interaction that workers generally and teens in particular learn about themselves (13).

For the adolescent worker, positive and supportive relationships with coworkers and supervisors can bolster autonomy, feelings of competence and self-esteem, and model self-regulation and engagement (4).

Conversely, experiences with abusive or authoritarian leadership may negatively influence relationships with other leaders as well as the teens' own sense of themselves as well as other work-related attitudes and behaviors (14, 15). There is evidence to suggest that adolescents are more influenced by their work environments than adults (16). Thus, the impact of positive or negative relationships will be greater for teen workers than older workers and, because of this intensity, the effects may also be stronger and more enduring (17).

Finally, a social learning perspective suggests that teens learn vicariously through observing behaviors of others and how they are treated may become how they treat others. Thus, teen's early work relationships may have immediate and long-term impact on identity, self-esteem and self-confidence, work attitudes, health and safety behaviors, job satisfaction and occupational attainment (10). Thus, examining adolescent work relationships and their impact on psychological, social, and job related outcomes is vital to our understanding of the value and impact of work for the developing adolescent and how we can respond as health professionals to address the impact of adolescent work experiences.

Unfortunately, research on adolescent work relationships is scant. There is a rich literature on vocational and career development, but until very recently it has tended to focus on work intensity rather than work quality (18, 19). Further, the focus in this research has been on outcomes in the domain of school and family and on problem behaviors such as substance abuse and criminality and much less on work-related and health outcomes (18, 19). The research that has focused on work quality has only recently begun to look into relationships with coworkers and supervisors and the impact on adolescent psychological and social development (4).

The adolescent development literature has tended to focus primarily in the domains of family, peer and schools with surprisingly little attention to the work context. (5, 18) The organizational and employment literatures that have focused on relationships at work generally and harmful relationships like aggression and bullying in particular have tended to focus on adults or on full-time work in organizations whose employees tend to be adults (19).

Indeed few studies have considered adolescent workers at all and those that do have utilized different definitions of young workers. The ILO defines young workers as 15-24 year olds (1). This includes early and late adolescents as well as "emerging" adults, clearly not a homogenous group. Most research in bullying has focused on adult workers, occasionally going as young as 18, leaving the 15-17 year old group untouched. Thus, this review will focus primarily on studies focused on the mid to late adolescence, i.e., the 15-19 year age group.

In this article, I will provide a brief overview of what is currently known about workplace bullying and its effects. This will provide a context for exploring adolescent experiences with bullying on the job both in terms of vulnerability to exposure and unique impacts given who they are. I will finish up with a discussion of issues to consider in helping adolescents address workplace bullying.

WHAT IS KNOWN ABOUT WORKPLACE BULLYING?

Before exploring adolescent experiences with bullying at work, it is important to give a brief overview of what is currently known about workplace bullying involving adults (See 11 for further detail). First, bullying is relational. Bullying is a hostile relationship rather than an event and occurs with a particular actor (20). Who the actor is has an influence on the nature

and degree of the impact. Actions from coworkers, supervisors, and the public are often experienced very differently (21). Second, bullying involves repeated behaviors over an extended period of time. The behaviors involved are varied and often move from subtle and covert to overt and direct. The more frequent behaviors, particularly from organizational insiders such as supervisors and coworkers, tend to be indirect and often nonphysical. That is, workplace bullying actions are predominantly psychologically aggressive. The types of behavior include those that

- Focus on personal aspects such as name calling, demeaning remarks, belittling opinion, devaluing with reference to age, gender, race/ethnicity or appearance, gossip and rumors, and intimidating or threatening actions. These are behaviors that are not atypical among adolescents.; and
- Focus on work-related aspects such as excessive monitoring, exclusion from work or information, undue pressure, impossible deadlines, unequal distribution of work, and assigning meaningless tasks (11). Interestingly, the most frequently reported behaviors are passive in nature, i.e., the “failures to do” such as withholding information and exclusion. This makes it challenging both for the target and for observers and potential interveners to discern what is happening.
- Third, a key distinguishing feature is that such treatment is persistent, i.e., endures for long periods of time. In the adult literature, duration has varied from 1 month to over 10 years. In a recent university study, 1/3 of those who were bullied had endured it for over three years (22). This notion of persistency is critical as it is an important predictor of the nature and extent of impact. Fourth, bullying is a gradually evolving process with a tendency to escalate and draw in other parties to the interaction as actors, supporters, and observers (11). Thus, like school bullying, workplace bullying is a communal phenomenon (23). Unchecked, workplace bullying has the potential to spawn other such relationships thereby creating a hostile work environment where many workers are now “behaving badly”.

Finally, bullying is different than conflict between equals due to the existence of a power imbalance (11). The source of power may be pre-existing in the structure of the workplace (e.g., boss-subordinate; actors has control of rewards and punishments) or more social, such as influence that comes from acknowledged expertise, control of critical information, connections to powerful others, or general likeability (French and Raven, 1959). The power imbalance can also develop as a conflict escalates and one party becomes disadvantaged relative to the other. The importance of the imbalance is the potential impact on the target’s resources and ability to defend him/herself as well as the actor’s ability to continue their actions (20). This has implications for the nature and intensity of negative effects and highlights the importance of prevention and early intervention, as well as the necessity of strategies for remediation of effects.

ADOLESCENT VULNERABILITY TO WORKPLACE BULLYING

Given that little research attention has been paid to workplace bullying involving adolescents, prevalence data are scarce. However, we can get a sense of rate of exposure by

considering data from adult samples as well as data regarding prevalence according to occupation and work status.

In their review of the global literature, Nielsen et al. (24) conclude that at least 1 out of 10, and perhaps as many as 1 out of 5, workers are exposed to bullying in their workplaces. There is variability by country and by region of the world. For example, the European Working Conditions Survey (EWCS) in 2010 reports an overall rate of 4.1% with country rates ranging from less than 1% in Poland, Bulgaria, and Italy to almost 10% in France (25). The US literature reports rates from 10-14% (19). These rates apply to direct targets. Extending the victim net to include witnesses, results in a dramatic jump in rates of exposure to workplace bullying. For example, in a representative sample of over 7000 US workers, 12.3% of respondents indicated they had witnessed others being bullied at work in the previous 12 months (26). Adding to this the 12.6% who said they had been bullied during this same period, almost 25% of the American working adults (18 years and older) are exposed to and affected by workplace bullying in a 12-month period.

With respect to age, younger workers appear to face similar rates of exposure as older workers. The EWCS reports little difference between 15-29 and 30-49 year old categories (4.2% and 4.3% respectively) while the age 50 plus category show a lower rate of 3.7% (25). The 2010 Zogby Survey of a representative sample of 2658 working adults (18 yrs and older) found a similar pattern of results with workers of age 50 plus having less exposure (9%) in the past year than 18-29 and 30-49 age groups of 11% each (27). Younger people did report witnessing more bullying (20%) than 30-49 and 50+ at 16% and 13% respectively. However, with both surveys, the category of young worker encompassed both adolescents and young adults. These two groups are at very different places in terms of their social and cognitive development. To get an idea of what adolescents' experiences with working relationships are like, I now turn attention to research on other negative work relationships.

The related area of workplace sexual harassment of young workers, particularly mid-to-late adolescents suggests that teens may be at greater risk for exposure to workplace bullying. Fineran (28) found that 39% of female and 30% of male high school students report being sexually harassed on the job. Fineran and Gruber (29) found that 52% of employed high school girls in their sample experienced some form of sexually harassing behavior in the past year on the job. These numbers are substantially higher than the workplace bullying rates reported above. Interestingly, research utilizing an adult sample found generalized forms of workplace harassment like bullying were more frequent than sexual or racial harassment (30). Taken together, these studies suggest that the rates of teen exposure to bullying may be higher than for older workers.

Another reason to expect that the prevalence rates from these representative surveys may be an underestimate is that the source of the bullying is not identified, i.e., the actor. Source is often associated with differential rates of exposure and impact (21). Thus, rates will vary dependent upon who the actor is. For example, North American research has found that bosses were more frequently the source of emotionally abusive behaviors for young (18-19 year old) workers while adult workers were equally likely to report bosses and coworkers as actors (31, 32). In terms of impact, aggression from organizational insiders (coworkers and supervisors) has more "meaning" and thus greater effects for workers than aggression from customers and the public (33). Hostile behaviors from supervisors have a greater negative impact than behaviors from coworkers (34). Given the developmental tasks that define adolescence such as identity and autonomy, the potentially unique significance of work and thus work relationships

for these tasks, and the propensity of teens to be more impacted by the work, teens may in fact be more vulnerable to bullying than adults.

RISK FACTORS FOR WORKPLACE BULLYING

Baillen, Neyens, De Witte and De Cuyper propose three interrelated pathways to workplace bullying: intrapersonal, interpersonal and intragroup/organizational (35). Individual and work-related antecedents are implicated in either being the source of these processes or influencing how workers cope with the challenges created by these processes.

The Intrapersonal pathway is one in which workplace bullying is a result of stressors and frustration and how employees cope with them. Research in this area focuses on individual characteristics that may enhance vulnerability to be a target or propensity to be an actor. Relevant target characteristics are those that may affect what the individual perceives as occurring (i.e., interpreting ambiguous behavior or situations as hostile) or may provoke affective and behavioral reactions that are provocative to others (submissive or provocative victims) or make them seem as “easy” targets for displaced aggression (36). Individuals with a propensity to experience negative affect such as anger, fear, and worry, anxiety, sadness and depression report higher levels of hostile treatment (37, 38, 39, 40). Similarly, relevant actor characteristics associated with increased aggression are ones associated with anxiety or anger and hostility such as negative affectivity, trait anger, poor self-control, emotional susceptibility and irritability, dispositional aggressiveness, (hostile) attributional bias and unstable self-esteem as well as lack of self-reflection and poor perspective taking ability (11,41-43).

What is interesting about these characteristics is that they map closely on to characterizations of adolescence as a period when negative emotions are more predominant than at other stages of life (44). It is also a stage at which emotional regulation and management are still developing. Given that successful regulation of emotion is central to functioning in interpersonal relationships and coping with challenges, generally, adolescents are at risk for interpersonal difficulties (44). Anger is of particular relevance as it has been associated with aggressive expression (45). Thus, it could be argued that adolescents may be more prone to anger or other negative emotions and that this can drive not only their behavior but also their perceptions of others' behavior. For example, research on teen workers' experience of abusive leadership suggests that teens may perceive leader behavior more negatively (i.e., label it as abusive or bullying) and, in turn, may be more negatively impacted by it (14). Adolescents are also more accepting of aggression and violence as a means to addressing frustrations (19). Research on affect and young workers found that anger was a frequent emotional response to perceived mistreatment and that young workers were more likely to respond with aggression than older workers (33, 45). Thus, the evidence suggests that, due to their emotional competence, teens may not only be more likely to perceive or interpret others' behavior as hostile (and thus, higher rates of bullying reported) but they may also be more likely to behave aggressively themselves, i.e., at greater risk for being bullies or provocative victims.

The Interpersonal pathway is one where workplace bullying may result from interpersonal conflict that is ineffectively managed and escalates, i.e., dispute-related bullying (35). In escalated conflicts, everyone engages in increasingly hostile and damaging actions. These conflicts become bullying situations when one party becomes notably unable to defend

themselves yet the other continues on an increasingly punitive path. Indeed attempts by the target to actively address the issues are often unsuccessful and such failure is often tied to increasingly negative impact on the target (47). Given that work is inherently relational, effective performance at work demands being able to develop and manage relationships effectively, which means being able to handle conflict. Evidence suggests that teens have had little practice with constructively resolving interpersonal conflict (48, 49). To the extent teens do not have either the skills or confidence in their ability to handle differences or to express their concerns constructively, disagreements can escalate into increasingly aggressive interactions. Such interactions can put the teens at risk for becoming either the victim or the bully.

The intragroup/organizational pathway is one in which workplace bullying is a result of a group or organization's features that enable or directly stimulate bullying. Of particular relevance to this discussion of adolescent workers is the notion of enabling processes or structures whose (non)existence affect whether bullying is even possible (50). Two examples of enabling factors are 1) youth aggressive culture and 2) quality of working environments in which teens are employed.

Youth aggressive culture is closely linked to socioemotional and interpersonal competence discussed above. In their review of young workers and aggression, Tucker and Loughlin argue that adolescence appears to be a peak time for aggression and violence (19). They argue that adolescents appear to have a greater acceptance or tolerance for aggression and violence as a response to frustrations. Further, they note that in the broader community, teens are generally at greater risk for being victims and actors of aggressive behavior, e.g., problem behaviors such as delinquency and substance abuse. Thus, they argue that youth are primed for, and experienced with, aggressive experiences and the workplace would be one more venue for that to be experienced and expressed. Another relevant group influence is that of peers. The research on teenage deviant behavior indicates that peer influences are particularly strong during adolescence (51). This finding is relevant to the extent that workplaces, in which teens find themselves, such as fast food and retail establishments, are dominated by very young workers. Thus, the presence of young coworkers and supervisors perceiving slights and modeling aggressive behavior may contribute to loosening of norms regarding aggression and violence.

Qualities of the working environment that create stress and frustration for workers such as unfair or inequitable treatment (perceived injustice), lack of autonomy and decision control, poor communication, role overload, conflict and ambiguity and uncomfortable physical environments have been linked to aggressiveness at work (42). Bullying may be the result of ineffective coping with these stressors. Young workers, particularly teens, tend to work in lower level services industries such as retail sales, consumer services such as eating and drinking establishments and service industries that are characterized by these qualities (2, 10, 52). These are industries where rates of bullying tend to be higher. For example, according to ECWS 2009, hotels and restaurants (8%) and wholesale and retail trade (6%) have rates notably higher than the rate of 4.1% for the overall working population (25). Eating and drinking establishments are interesting workplaces from a workplace bullying perspective as they have a number of risk factors including

- Being predominantly staffed by young coworkers and supervisors (i.e., less experienced, lower emotional competence, greater likelihood of aggression and conflict);

- The presence of job stress in the form of time pressure and customer demand (18). Stress has been associated with aggressive behavior, particularly in teens.
- Restaurants, in particular, have bullying ingrained as part of the culture (53). For example, chef apprentices report higher rates of exposure to bullying than other workers in the restaurant.

In addition to the industry, teen workers typically occupy entry-level positions and are often part-time or temporary (2). Thus, in the organizational structure, teen workers are at the lowest level of the hierarchy and potentially at risk for hostility from higher ups.

Youth are also vulnerable because of their limited mobility due to 1) being placebound by virtue of living at home and/or attending school and 2) lack of alternative employment as there are fewer jobs at the unskilled or limited skill level, a situation that has worsened during the current global recession. Thus, teens are less able to leave hostile workplaces and thus, less able to limit their exposure to bullying. Taken together, the workplace context, adolescents' relative position in the organization, limited mobility and their own social and emotional competence to manage interpersonal situations suggest that young workers are not only at risk for bullying but may be at greater risk for being both targets and actors than other age groups.

IMPACT OF WORKPLACE BULLYING

Given the unique developmental tasks and the socioemotional competence of adolescents, young workers are different in important ways from their older colleagues. These differences may influence the nature and degree of impact of exposure to workplace bullying.

In terms of nature of impact, the extant and primarily adult worker literature reveals that exposure to persistent aggression such as bullying has profound and often disabling effects on an individual's functioning across a number of domains including 1) disruption of cognitive, psychological, emotional and physical well-being; 2) decrements in job related attitudes and behaviors; and 3) strain in interpersonal relationships such as family and friends. (See 11 for review). While the range of effects is striking, what has been missed in the workplace bullying literature by not focusing attention on teen workers is the potential effects in the domains of school, family, and peers; domains viewed as critical influences on adolescent development and identity (18). More specifically, research on the costs and benefits of working for adolescents has targeted school involvement and academic achievement, career aspirations, family and peer relationships as well as problem behaviors such as drugs and alcohol, sexual behavior and other forms of delinquency (5). These are clearly important outcomes that should be considered in studies of adolescent worker experiences with bullying.

Of these outcomes, recent research with working adults suggests that workplace bullying can have negative implications for family and friendships as these individuals experience distress and strain of providing support for the targeted loved one and frustration at not being able to change the situation for them (54). Such strain can translate into increased conflict within the family or with friends, disrupting critical social support that is vital for helping the target deal with their current job situation. For teen workers, such strain and conflict may be even more problematic given the vital importance of family and peer relationship to overall identity development and the achievement of autonomy. Evidence from the adult literature on

bullying documents the development of problem behaviors such as alcohol and drug use as a way to self-medicate to deal with the mental and emotional issues associated with being a target of workplace bullying (47). In addition to substance abuse, the youth employment literature suggests that sexual behavior and general delinquency would be possible outcomes to examine (18). These behaviors have long-term implications for adjustment into adulthood. In terms of school outcomes, Fineran and Gruber study of workplace sexual harassment found evidence of school avoidance and academic withdrawal (29). While disruption of school is a serious outcome in its own right, by affecting school engagement, workplace bullying may also indirectly influence subsequent career development. Self-efficacy is another important outcome to explore for teen workers. MacMillan and Hagen found a negative link between victimization and self-efficacy (55). Mortimer and Staff's longitudinal study of young workers found that job stress affected self-efficacy at 4 and 9 years post high school. Lubbers et al. showed that self-efficacy influenced subsequent job performance and even physical health at later periods of time (57). These results suggest that teen exposure to workplace bullying may have important long-term implications for not only health and well-being but also for key relationships, academic achievement, career development, work behaviors, and ultimately occupational attainment (Frone, 1999).

As noted earlier, teen workers may be more affected by job experiences than older workers due to their relative inexperience as well as their socioemotional competence. Thus, the above described effects may be even more damaging for young workers. However, there are factors that may moderate such impact. For example, degree of investment in or identification with work has been shown to moderate the impact of work experiences on the individual (33, 56). Applied to teen workers, this suggests that the intensity of impact may be lessened to the extent the teen does not see work as a central part of their overall identity. Greater attachment to and opportunities for achievement and autonomy in the other domains of school, family and peers may offset the impact of workplace bullying on teen's sense of self and self-efficacy. Further, relationships in these domains, assuming they are constructive, could provide support in terms of reframing the experience to be less damaging to the teen, i.e., it is not their fault as the actor is being unfair or inappropriate, and/or by simply providing distraction so that rumination on the work experience does not occur (18).

In sum, workplace bullying can have broad ranging and particularly intense effects on teen workers; effects that may have enduring implications for both general and occupational development into adulthood. Its effects are not limited to the work domain but can spillover and potentially disrupt life in the domains of school, family and peers. It is important that research and practice focus specifically on teens' experiences at work, particularly their relationships with coworkers and supervisors, and examine impact on functioning across diverse life contexts.

IMPLICATIONS FOR HEALTH PROFESSIONALS

This review has highlighted the exposure risks and potential impact of hostile working relationships on adolescent development and well-being. Such findings have implications for health professionals working with teens in at least three areas: 1) assessment, 2) treatment/intervention, and 3) employment preparation. Work is clearly an important life

domain for adolescents and should be included in any assessment of mental and physical health. Most simply, teens should be asked about experiences on their jobs. Exploring the nature and quality of work relationships and the impact on the teen's cognitions and feelings about themselves, their own efficacy, and competence would be important. An examination of how the teens are processing these experiences as well as their understanding of their own responses may help illuminate areas for intervention. Based on the evidence of domain spillover, it would also be important to examine how these work experiences connect to issues and relationships with family, peers, and schools. Examining how relationships and experiences in these domains may buffer, address, or exacerbate the impact of work experiences would provide important information regarding coping and support and ways to bolster adolescent resources to respond.

In terms of treatment and intervention, educating the teen about workplace bullying and distinguishing it from normal conflict and employment discipline processes would help raise an adolescent's awareness that such interactions are inappropriate and harmful. An analysis and understanding of the possible reasons for the bullying experience, e.g., intrapersonal, interpersonal, and/or intragroup/industry factors highlights specific actions for addressing the teen's experience (35). To the extent the sources are intrapersonal, i.e., emotional competencies of the teen, strategies would focus on helping teens develop more effective stress and emotional management strategies, particularly management of anger. If the situation is being fueled by deficits in interpersonal/social skills, efforts could focus on the development of the teen's relationship building and constructive conflict management strategies such as listening, assertion, and problem solving. In addition, facilitating teen skill development in presenting problems to their work supervisors would also be important, i.e., constructive help seeking. To the extent the hostility and bullying is a quality of the particular workplace (job risk), the health professional can help the teen see how the environment is unhealthy and beyond their ability to control, i.e., not their fault. Engaging the teen in systematic job skill and vocational interest assessment can help a teen develop a realistic sense of their strengths and career goals. Pairing this with concrete skill development in resume writing and interviewing would help the teen find more constructive work and work environment and through this process contribute to their sense of efficacy and competence.

The intervention strategies noted above all focus on building teen competency and resiliency. Complementary actions could include drawing in significant others (family, friends) and helping them understand the challenge faced by the teen and the ways in which they could provide support for the individual. Examples of such support could be helping the teen understand the experience (e.g., reframing, reattribution) and/or providing quality experiences in other domains that bolster teen self-esteem and self-confidence or simply provide a pleasant distraction and preventing harmful rumination.

At a broader level, health professionals would be important resources in discussions of how we approach preparing teens for working and the work world. For example, work-study or cooperative programs with high schools and workplaces are a mechanism for introducing teens to work as an educational experience under a careful and thoughtful joint school-workplace supervision model. Another approach is the apprenticeship model, in which the teen works closely with an adult who is a master in a particular trade or occupation. Both these mechanisms are (or should be) grounded in an understanding of adolescent and vocational development and the importance of thoughtful mentoring, skill development and guided self-reflection. Within these contexts, working relationships can be explored, skills taught, and teens can raise their concerns for thoughtful analysis and constructive feedback.

CONCLUSION

Work is a critical life domain for adolescents that can have profound and enduring effects on their pathway to adulthood. Teen workers' relationships with their coworkers and supervisors are particularly important in terms of the quality of the overall work experience and providing the social context in which the meaning of working is constructed. When these relationships are hostile, undermining and destructive, the effects on teens' health and well-being, self-efficacy, identity and vocational goals can be profound. Further, these effects can be felt in other life domains such as family, peers and school and can be enduring, influencing the teen well into adulthood. Unfortunately, little is understood about teens' working experiences and work relationships generally, and hostile and bullying relationships in particular. This review of the extant and related literatures suggests that teens are exposed to workplace bullying and may indeed be at greater risk for both exposure and for the nature and intensity of harm by virtue of their stage of life development and the nature of their workplaces in which they find themselves. It is hoped that this review provides important information and suggested directions for health professionals and researchers to pursue in identifying and addressing the challenges teens face in their working relationships.

Chapter 77

BULLYING AND GANGS

Rob White*, PhD and Ron Mason, MA

School of Sociology and Social Work,
University of Tasmania, Hobart, Tasmania, Australia

ABSTRACT

Although bullying is associated with gangs, questions arise as to whether bullying, as such, takes place within gangs. In this chapter we will provide a critical analysis of bullying as this pertains to youth gangs and especially to violence within gangs, and as applied to the behaviour of individual gang members. We will talk about young men between 12 and 25 years of age and review relevant literature with a view to theorising the nature of the relationship between bullying and violence within a youth gang context. Bullying is associated with the reasons why individuals join gangs and with gang-related behaviour, but the violence within a gang is of a different character than that usually described by the term bullying. Bullying has implications for related and/or subsequent types of street violence, but is less relevant for descriptions of violence within a youth gang context as such.

INTRODUCTION

Two issues of concern have become especially prominent in media and research discussions of youth behaviour in recent years: bullying and youth gangs. A substantial body of literature exists on both of these social phenomena, and likewise there are major ongoing efforts to devise various types of (early) intervention programmes and desistance strategies. A strong connecting point between these literatures is the focus on violence (variously described but that includes physical through to psychological aspects), and the risks and actual harms to individuals stemming from gang and bullying behaviour. Interestingly, many of the strategies designed to short circuit bullying and gang-related behaviour are likewise similar in nature,

* Corresponding Author's Email: r.d.white@utas.edu.au.

with a stress upon early intervention and holistic approaches to personal and community development (1,2).

This paper explores the relationship between gangs and bullying by considering two key questions:

- Is there a causal association between participation in bullying and participation in youth gangs? and;
- Does bullying take place within youth gangs?

For present purposes the term ‘bullying’ is used to refer to behaviour characterised by a distinct type of repeated aggression and a systematic abuse of power (3). In essence, bullying is about the exercise of power that simultaneously makes a social statement about the worthlessness of the victim. The definition of ‘gang’ is contentious, but generally speaking it refers to street present young people who regularly engage in violence and criminal or delinquent behaviour (4).

An underlying assumption of this paper is that in addition to violence per se being a link between bullying and gang behaviour, a further link pertains to the gendered nature of the violence. That is, most physical aggression is tied to masculinity and the self-perceptions and self-images of boys and young men, particularly those from the working class (5). The construction of violence as a working class phenomenon partly stems from the importance of physicality - the body - in working class life and culture. Traditionally paid work was largely reliant upon performing physical tasks (in the factories, in the mines, in the trades, in the army). The centrality of physique and the physical translates into forms of aggressive masculinity which celebrate strength, speed, agility and general physical prowess.

While considerations of masculinity help to frame with issues of violence (in the school yard as well as in the street), we are still left with intriguing questions regarding how different forms of violence are related to each other, and how they overlap. These questions thus return us to further exploration of the relationship between bullying and youth gang behaviour.

CRITICAL REFLECTION

This chapter relies on literature dealing with gangs and bullying in order to offer an interpretive conceptualisation of the relationship between these social phenomena. The ‘methodology’ therefore is less that of empirical study than critical reflection. Even so, there are distinct matters that nonetheless have to be addressed. For example, in gangs research, ‘One of the key methodological issues in the study of gangs has been whether the unit of analysis is the gang, the gang member, or the act (crime) committed by the gang member or members’ (6). This is worth exploring in order to illustrate the analytical conundrums associated with gang research.

There are major difficulties in defining what a gang is (7-9). So, too, there are major problems in trying to identify who a gang member is and their precise relationship to a particular youth group formation. The question here is not so much the presence of the group, but a particular individual’s involvement with that group. Group membership is largely a fluid process, with specific individuals having varying degrees of association over time.

Consider for example the following. A young person may occasionally associate with a 'gang', but not be a member. A young person may participate in the activities of the 'gang' once in a while, but not be a member. A young person may desire to be a part of the 'gang', but not actually become a member. A young person may say they are part of the same crowd or 'gang', but not actually be a member of the relevant core group. A young person may have all the external trappings of a gang member (street gang culture in the form of dress, posture, talking style) but not be a member of a gang.

Gang membership is not absolute or fixed, but highly variable and changing. Indeed, there is often no clear dividing line between those who are in a gang and those who are not. Being a member of a 'gang' is generally a contingent process, one defined by specific activities, special relationships and specific networks at any particular time (10,11). Gang membership also tends to be marked by different degrees of commitment and association. Any particular group tends to be loosely organised around a core group (the hard core or leaders), fringe members (who participate in gang-related activities on a less frequent basis), and 'wannabes' (those who aspire to be hard core members of the main group). Again, these categorisations are fluid and may not always apply to actual group formations. People could drift in and out of particular youth formations, including those self-described by the young people as 'gangs'. For some, it is a short-lived passing phase, for others it might constitute a longer-term commitment.

It is not only perception by others, but self-perception, that is crucial to the development of gang identity. Sydney research has found, for example, that some of the young men who were interviewed presented themselves as a 'gang' in order to gain a measure of 'respect' (12). The symbolic representation of themselves as members of a gang, however, was more at the level of overt performance (i.e., presenting an image of being tough and dangerous), than in relation to particular kinds of professional criminal activity. The point of claiming gang status was to affirm social presence, to ensure mutual protection and to compensate for a generally marginalised economic and social position. Significantly, research indicates that where young people themselves claim gang membership, they tend to engage in substantially more anti-social and criminal behaviour than those who do not profess to be gang members (13,14). Who you say you are thus has implications for what you do and with whom. Group identification is thus intertwined with group activity.

Various kinds of group formations (e.g., gangs, crowds, peer groups, subcultures) and different kinds of violence (e.g., riots, mob action, street fighting) are linked in the sense that certain key attributes tend to feature across much of what occurs in public spaces such as city streets (15). For example, work undertaken on violence and masculinity demonstrates a strong cultural component to violence, especially for males (16,17). Particularly for working class young men, physical prowess or toughness is a form of social capital. In most social milieu, a young man's reputation depends in part upon the credible threat of violence (17). Quick resort to physical combat – as a measure of daring, or courage, or defence of status – appears to be a standard cultural expectation, especially for working class boys and young men. This perhaps explains the widespread nature of violence among school-age male populations. That is, in a context in which 'manhood' is yet to be proven by attainment of paid work, marriage, leaving home or beginning a family of their own, physicality itself, relying upon the body, is one way in which to 'prove oneself' (5). This would therefore help to explain the prevalence of male violence across the schoolyard, if not the intensity and differences in manifestation.

BULLYING

Bullying has major effects on perpetrators, on victims and on observers. Moreover, those who bully may themselves be on the receiving end of bullying, at school, at home or on the street. The consequence of bullying lies in individuals changing their personal behaviour, from avoiding certain places at certain times of the day, through to becoming more aggressive and lashing out at those around them. Bullying can involve one-on-one confrontations, or groups that pick on specific individuals and/or social groups. The dynamics of bullying are structural, situational and individual in that they involve social differences between participants (such as ethnic or class differences), interactional factors such as the presence or absence of observers (including guardians) and personal dispositions (such as propensity toward aggression). It is the complexities that surround bullying that can lead researchers to conflate bullying and gang behaviour.

For young people, engagement in bullying or gaining protection from the threat of physical violence may be important motivations for joining a gang. For instance, when considering the effects of bullying at school in relation to gang-related behaviour, research has found that bullying is a strong predictor of anti-social behaviour and development (18); that self-reported bullying at a younger age (14 years) increases the likelihood of violent convictions between ages 15 and 20 years and self-reported violence at age 15-18 years (19); and that school bullies are much more prone than non-involved students for later offending (3). Being a bully means being used to violence. It also means associating violence with everyday activities, including those experienced as pleasurable or fun, as well as those denoting street status.

Conversely, it has also been shown that repeated exposure to being bullied can undermine the health and wellbeing of vulnerable students (1), and harassment frequently has its roots in social prejudice (e.g., gay students, those from ethnic minorities). Being bullied at school is significantly associated with being bullied outside school (20). It is notable that in New South Wales between 2005 and 2009, there was an upward trend in the rate of recorded assault incidents between school-aged children on government school premises during school hours, generally involving two students of the same gender (generally boys), aged between 13 and 15 years (21). Such violence begets violence, especially when combined with structural inequalities and social differentiation. It has been observed that 'from the perspective of a marginalized individual living in a marginalized community who has suffered considerable personal trauma, the gang can be an effective mechanism for supporting violent aggression in what appear to be irrational ways' (6). Personal tragedies, including being victimised, can affect children and young people in ways that put them on a trajectory toward gang involvement.

Interestingly, English research has found that a bigger proportion of young people are more worried about being physically attacked than bullied (22), hence implying that occasional violence, including group violence is ever-present and all-pervasive in schools. This has also been found to be the case in Australian youth gangs research (14) which found high incidences of school based gang violence and individual non-gang violence. At a formal definitional level, bullying refers to repeated behaviours that involve a wide range of physical and non-physical harms, but that are targeted at the same individual. What some of the gangs research shows is that students are not only concerned about this kind of targeted, specific violence (i.e., what we usually think of as bullying), but the more randomised forms of violence where you are never quite sure who is going to attack you and for what reasons (e.g., the Australian study showed a

lot of violence involving non-gang students, usually of a one-to-one kind, as well as group based violence linked to youth gangs). The triggers to violence are often situational (e.g., accidental bumping) as well as occasionally linked to intentional bullying. Overall, the extent of violence is of considerable concern to students and contributes to a general anxiety about being physically attacked.

Racism and prejudice can frequently exist as precursors to violence, as well as being forms of structural violence in their own right (7). This is evident in the ways in which racialisation of the gangs debate in places such as Great Britain, Australia and North America is stigmatising certain population groups (9). Having said that, however, bullying and gang formation cuts across actual colour or religious divides and is about territory and neighbourhoods. In regards to territoriality, young men protect themselves by posing as dangerous and 'bad', and by behaving and dressing aggressively (23, 24). How they do so, however, may plug back into wider racial and ethnic stereotypes. For instance, 'In street culture, negative stereotypes from mainstream society can provide protection and status....symbolic signs associated with the category 'foreigner' can be conceptualized as a form of embodied street capital.' (24). Gangster images combined with ethnic markers and aggressive physicality may well provide group protection in what are generally hostile social environments for minority groups (12).

While there are sound reasons to accept that bullying may help to propel some young people into gangs – either for protection or for enjoyment – the activities of youth gangs are not reducible to bullying type behaviour as such. This is because of the specific character of youth gang violence. Thus, for example, 'youth gang-related violence mainly emanates from inter-gang rivalries, turf protection and expansion, and interpersonal disputes or "beefs"' (23). The nature of the violence is intrinsically dictated by the nature of the group formation. In such a context, bullying may, in some circumstances, be frowned upon insofar as it does not reflect a legitimate avenue for the expression of 'manhood', 'masculinity' and 'machismo' associated with gang identity, peer solidarity and group status.

Indeed, the specific cultures and rituals of gangs are essential to consider when it comes to how violence is perceived and experienced by gang members. For example, gang induction may require initiates to endure a character test in what are called "beat-downs" or "jump-ins" (23). Is this bullying? Not really, since the violence is welcomed by the recipient and interpreted as empowering rather than an imposition of power. Street culture more generally also demands ongoing character tests that involve constant affirmation of dangerousness and ability to fight (24), essential gang member attributes. In other words, violence within the gang, and on the street, is expected and routinised.

The motivations for gang violence include such things as retaliation, which is related to the group aspects of violent acts. Groups of young men who are regularly vilified and subject to street taunts and attacks may band together and become a gang for the purposes of protection and symbolic strength (12); these same people experience racism from teachers at school (subjectively experienced as a form of 'bullying'). On the other hand, rivalries between defined groups may involve 'picking on' a specific individual (from the other side or gang); but this in turn needs to be interpreted not as individualised bullying but part of a collective social dynamic.

Gang violence may be experienced as 'fun' by participants, in the sense that it provides an adrenaline rush and is associated with 'typical' working class masculine pursuits that define a 'top night out' such as drug taking, drinking and fighting (25-27). Not surprisingly, then, 'Groups of men with a history of fighting often evolve into gangs in the Russian context' (6),

an observation that has Australian equivalents (10) and that resonates in other cultural and national contexts as well (7).

At both personal and group levels, gang violence provides a particular type of expression of masculinity. Indeed, fighting is seen as a proof of manliness, regardless of whether you win or lose (26). In the context of both a 'will to violence' (27) and a cultural association between violence and masculinity (28), the gang provides a ready-made forum for the expression of individual aggression.

How you fight (with fists or with other weapons) is also connected to conceptions of manliness (10). More generally, the interpretation of violence is defined in terms of 'rules of engagement' that act so as to 'render violence intelligible and rewarding for those who participate in it' (29).

These rules refer to violence within the gang such as initiation and fights between gang members, as well as external violence. For example, gang-related violence is often guided by rituals of restraint when a gang member fights another member of the same gang, whereas 'outsiders' are more likely to suffer from a no holds barred approach. Gang responses to and engagement in violence are thus typically defined by the situation, not by the characteristics of the perpetrators as such.

In some cases, there is the perception at the street level that some types of 'violence' are not really violence. For example, a 'fair fight' is not violence, but 'Violence occurs when the rules are broken. Violence is that which is unpleasant and morally non-defensible, like attacking smaller guys, using weapons, stamping on somebody who is lying down or putting your foot in somebody's face' (24). In Oslo, then, the rules not only guide behaviour but they also guide interpretation.

From one point of view, violence may well be seen as rational in particular situational contexts. For example, force or violence may be viewed as rational behaviour to the extent that it is designed to effect change in the target of violence. Furthermore, many young people fight not because of an absence of values, but because of values that hold such behaviour to be a justifiable, commonsense way to achieve certain goals (30). This is especially understandable in the context of concerns about masculine identity, and violence that relates to defence of 'male honour' (17). But the rationale behind the violence need not be simply due to cues or triggers imposed externally.

There is increasing evidence that violence also stems from the efforts of young people themselves to engineer situations and events with the intended aim of increasing the likelihood of violence occurring (26, 27).

From this perspective, the gang provides a forum or ready-made opportunity structure within which to engage in what is felt to be exhilarating activity. Fighting is fun; and gangs provide an avenue to increase the thrill factor beyond the norm. Violence can thus be seen to be attractive and desirable in its own right, as well as being linked to instrumental purposes (14). Group violence achieves a number of rational, emotional, psychological and social purposes, simultaneously.

DISCUSSION

Bullying has become a ubiquitous term to describe all manner of conflict between individuals and groups, with particular emphasis on bullying among adolescents. Definitions

of bullying have changed over time to include more phenomena being associated with or descriptive of bullying, especially non obvious, indirect forms of bullying such as exclusion (1). This change also includes reference to the commonly held belief that bullying involves one individual bullying another individual. Later research has identified a group basis to bullying where a group either bullies an individual or another group (1). Thus the definition of a bully has expanded from traditional perceptions of the bully as primarily individually based, to include the group as bully.

In the context of an expanding definition, it becomes difficult to separate bullying from other forms of potential and actual conflict or violence between individuals and groups. That is, very little differentiation exists – given current definitions – between bullying and general conflict/violence, in relation to both its antecedents and expression. However, what does appear to be a common thread is the power relation between individuals and groups. Those physically stronger, or culturally dominant, are able to persecute others through perceived difference and weakness relative to themselves. Marginalisation equals vulnerability to bullying by others. Be marginal at your own risk.

Bullying is persecution that includes picking on, intimidating, slandering or assaulting an individual or group which is vulnerable to persecution. An individual or group that displays weakness is physically or culturally marginal or vulnerable relative to the other individual or group. The definition of ‘other’ is crucial to the act of bullying, since without the sense of ‘other’ (that is, not us or not normal), bullying generally does not occur.

It has been suggested that two key characteristics separate bullying from other aggressive behaviour; repeated victimisation, and a power imbalance, with bullying taking various forms including, physical, verbal abuse, social exclusion and indirect forms such as spreading rumours (20). Bullying behaviour thus may include name calling, verbal or written abuse, exclusion from activities, exclusion from social situations, physical abuse, or coercion. Bullies may behave this way to be perceived as popular or tough or to get attention. They may bully out of jealousy or be acting out because they themselves are bullied.

Bullying is typically defined as either one individual or group threatening or intimidating a targeted individual (31). Australian studies have shown that race or ethnicity is significantly associated with peer victimisation (1). Other Australian research has indicated that racism is expressed through being unpleasant, verbal abuse, exclusion, avoidance and physical assault (32). Note that those actions/behaviours described by young people to describe expressions of racism are also those behaviours that define bullying. If the above definition is accepted then the question becomes; “How does bullying differ from other forms of conflict between young people”? Is all conflict based on bullying? Indeed, in some circumstances those actions described as bullying can be a tactic or opening gambit for negotiated violence among young people, especially slurs and insults (30).

Additionally, there is no ‘typical’ bully or victim, each can be one or the other depending on circumstance; there are, then, “bully-victims”. Other roles include defenders (those who protect the victim) and bystanders (onlookers) (20). Again, this observation begs the question of how do these roles differ from the roles observed in general conflict/violence between people, especially group based conflict such as gang fights. All group based conflict exhibits these roles; there is nothing about either the definition of bullying or the roles observed that makes them specific to bullying.

As mentioned above, the definition of an individual or group as ‘other’ is inherent to bullying and the ‘other’ must be vulnerable in a physical and/or cultural sense; they must be in

a weaker position relative to the bully(s). Factors associated with bullying include race, ethnicity, gender, disability, sexual orientation, and peer group (having few friends or untrustworthy friends). Within a sociocultural perspective bullying has its roots in social prejudice (1).

Peer/friendship groups are generally formed on the basis of common interests and purposes and to provide support for group members. They may also constitute a threat to outsiders, sometimes to ex members, who they may bully (1, 32), with the act of bullying in this case constituting a challenge to the 'other' to fight. Slurs are traded until the point of violence or retreat by one party. The act of bullying within a group context then, is the basis of negotiated conflict between groups of young people.

Situations arise whereby young people are members of a group that is more powerful than another group. Bullying may be motivated by a grievance or prejudice, rivalry, or simply to have fun at the expense of another. These acts of bullying are typically initiated and sustained by the connection with a group rather than driven by individual motives, this view presupposing that bullying is typically a group phenomenon.

It would thus appear that the type of bullying undertaken and the motives for bullying are dependent upon the context within which it occurs. Typically, schoolyard bullying is where the normal rules of restraint do not apply. Bullying is not restricted to settling a gripe or asserting status in a one off opportunistic situation but is the systematic, ongoing persecution of another over time. The continual targeting of an individual or group is based on some psychological (introverted, shy), physical (puny), or cultural (gay, ethnic) attribute. The target is seen as 'other', because they generally belong to a marginalised group or are 'self' marginalised.

Gang violence may likewise involve bullying individuals and groups outside of the gang itself. Gang rivalry, for instance, involves mutually recognised antipathy. In this social context, each individual is always seen as gang member, even when alone. An individual's membership of a gang makes them vulnerable when they are not with the gang. They may not only be vulnerable to bullying by other rival gang members but also by young people who are not a member of a gang. Their membership in a gang thus makes them vulnerable to bullying by others, especially when they do not have other gang members around to protect them.

With respect to this, Australian research has suggested that gang members are significantly more likely than non-gang members to report that other students pester or persecute them and that they dread going to school (32). Moreover, when asked why young people join groups a significantly greater proportion of gang members than non-gang members reported that they joined the gang for protection. When present in numbers, the gang may provide a defence against being bullied, both by individuals and other (competing) groups.

The motives for bullying in a gang context may be different from those where an individual is bullied either by a single person or a non-gang peer group. Gang bullying is not only about degradation or aiming a statement about the worthlessness of the individual; it is a tactic used as part of ritualised violence. It is not persecution per se, but rather an opportunistic behaviour aimed at asserting physical and thereby social dominance over a rival group. It is interesting in this regard to note that ex-gang members are not usually put into the category of the 'other', as indicated in research that reveals that gang members can normally leave the gang without serious consequences (23).

In conclusion, although bullying is associated with the reasons why individuals join gangs, the violence within a gang is of a different character than that usually described by at least some

definitions of bullying. But gang members can and do ‘bully’ outsiders. Thus, there is an association between bullying and gangs, but this association is more complicated and layered than may at first appear.

Chapter 78

BULLYING VICTIMIZATION AMONG 13 TO 15 YEAR OLD SCHOOL CHILDREN: RESULTS FROM TWO COMPARATIVE STUDIES IN 66 COUNTRIES AND REGIONS

²Institute of Public Health, University of Copenhagen, Copenhagen, Denmark

ABSTRACT

This chapter will examine the prevalence of bullying victimization in 66 countries and territories from five continents. The study was based on data from two large international surveys: the 2001/2 Health Behaviour in School-aged Children survey (HBSC) and the Global School-based Students Health Survey (GSHS). The surveys provide nationally representative, cross-sectional information on 13-15 year old school children (N=218,104). Outcome Measures: Bullying victimization, once or more within the past two months (HBSC)/30 days (GSHS). Results: On average 32.1 % of the children were bullied at school at least once within the past two months in countries involved in the HBSC study and 37.4 % of children were bullied at least one day with the past 30 days in countries involved in the GSHS study. In both surveys, there was large variation in prevalence across countries. The lowest prevalence in the GSHS survey was observed in Tajikistan (7.1% for both boys and girls) and among HBSC countries in Sweden (16.0 % for boys and 14.6% for girls) and the Czech Republic (17.1% for boys and 14.2% for girls). The highest prevalence for boys in the GSHS survey was found in Zimbabwe (Bulawayo) (70.2%) and for girls in Zambia (67.1%). In the HBSC survey, Lithuania had the highest prevalence of bullying victimization (62.7% for boys and 64.4% for girls). Conclusion: Victimization to bullying violates the fundamental rights of children and our study suggests that many countries who signed the Convention on the Rights of the Child need to work harder to fulfill the goals.

INTRODUCTION

The Convention on the Rights of the Child under the Charter of the United Nations (1) states that ‘the child should be brought up in the spirit of the ideals proclaimed in the Charter of the United Nations, and in particular in the spirit of peace, dignity, tolerance, freedom, equality and solidarity’. The convention was ratified by 140 nations by July 2007. Environments that allow bullying victimization violates children’s right to be brought up in the spirit of tolerance and solidarity, and the prevalence of bullying is therefore an issue of importance, not only nationally, but also internationally.

Bullying is defined as a deliberate, repeated or long-term exposure to negative acts performed by a person or group of persons regarded of higher status or greater strength than the victim (2). Bullying might be verbal acts such as threats, insults or nicknames or physical acts such as assault or theft. Also social acts such as exclusion from the peer group are considered bullying. Bullying is aimed at victims who cannot easily defend themselves (2,3) and is aggression beyond common teasing (4). Prevalence of bullying victimization decrease with age, and exposure to bullying is generally higher among younger children, with the youngest and weakest being exposed the most (2,3,5-7).

Bullying victimization is strongly associated with physical and psychological health outcomes (5,6,8-20) and seem to have long term consequences on health and well being of the individual (21-23). Moreover, victims of bullying have difficulties in establishing social relationships with peers (2,5,14,24,25) and some victimized children react by bullying others, to defend themselves or to bolster their self image, thus creating a vicious circle that is likely to increase the prevalence of bullying and its adverse effects (26). Further, bullying behaviour and victimization track over time (2,15,22), which means that many children are exposed to bullying for years.

Since the first seminal studies on bullying were conducted in Norway and Sweden (27,28) national studies have found bullying to be a prevalent behaviour among school children in a wide range of countries (5,6,8-14,17,19-20,29). Publications from the international Health Behaviour in School-Aged Children (HBSC) study have generally confirmed data from national studies (18,24), but have shown that there are large international differences in the prevalence of bullying. The HBSC study, however, only comprises countries from Europe, North America and Israel.

This study used data from two large international surveys to examine the prevalence of bullying victimization among of 13-15 year old boys and girls in 66 countries and territories from five continents.

DATA THAT WE USED

We used data from two internationally comparative school-based surveys. Health Behaviour in School-aged Children (HBSC) is a standardized, international WHO collaborative study with repeated cross-sectional surveys among 11, 13 and 15 year old students in representative samples of schools in the participating countries from Europe, North America and Israel (30). The data collection is based on an internationally standardised and validated questionnaire. The study aims to gain new insight into young people's health and well-being,

health behaviours and their social context. This paper reports data from the 35 participating countries and territories in the 2001/2002 survey.

Each national study included students in the relevant age groups (11, 13 and 15 year olds) from a random sample of schools. The present paper uses HBSC data from 13 and 15 year olds in order to compare with data from the Global School-based Health Student survey (GSHS) (see table 1).

Table 1. Bullying questions used in the Health Behaviour in School-aged Children 2001/2002 questionnaire and in the GSHS survey

HBSC 2001/2002	
Here are some questions about bullying. We say a student is BEING BULLIED when another student, or a group of students, say or do nasty and unpleasant things to him or her. It is also bullying when a student is teased repeatedly in a way he or she does not like or when he or she is deliberately left out of things. But it is NOT BULLYING when two students of about the same strength or power argue or fight. It is also <u>not</u> bullying when a student is teased in a friendly and playful way.	
How often have you been bullied at school in the past couple of months?	
1 ☐	I have not been bullied at school in the past couple of months
2 ☐	It has only happened once or twice
3 ☐	2 or 3 times a month
4 ☐	About once a week
5 ☐	Several times a week
GSHS	
Bullying occurs when a student or group of students say or do bad and unpleasant things to another student. It is also bullying when a student is teased a lot in an unpleasant way or when a student is left out of things on purpose. It is not bullying when two students of about the same strength or power argue or fight or when teasing is done in a friendly and fun way.	
During the past 30 days, on how many days were you bullied?	
A	0 days
B	1 or 2 days
C	3 to 5 days
D	6 to 9 days
E	10 to 19 days
F	20 to 29 days
G	All 30 days

Table 2. Prevalence of bullying in 66 countries and territories: percentage of 13 and 15 year old school children, who have been bullied at least once in the previous couple of months (Health Behaviour in School-aged Children (HBSC)) and percentage of 13-15 year old school children, who have been bullied at least once within the past 30 days (Global School-based Student Health Survey (GSHS)) by sex and country

Country	Study	Year of data collection	N of participants	Boys % bullied	Girls % bullied

^b Study level average (un-weighted).

The GSHS was developed by the World Health Organization (WHO) in collaboration with United Nations, UNICEF, UNESCO, and UNAIDS with technical assistance from the Centers for Disease Control and Prevention (CDC). The GSHS aims to provide data on health and social behaviours among school-going adolescents.

The GSHS survey comprises data on 13-15 year olds from 31 countries and territories from Africa (nine), the Americas (eight), the Eastern Mediterranean region (eight), the Western Pacific regions (five) and Europe (one).

As the GSHS survey is not conducted within any internationally distinct timeframe, we have used surveys conducted as close to the year 2001/2 as possible. We used data from the 31 countries and territories, where the survey included measures of bullying (31). All surveys were performed within the years 2003 to 2007, and the year of data collection for each country is presented in table 2.

In total, this study present results based on data from 218,104 students (sample sizes ranged from 596 in Greenland (all 13 and 15 years old Greenlanders) to 15,790 in the United Arab Emirates). In the HBSC survey, students answered a standardized questionnaire during a school

lesson after instruction from an adult (32) and in the GSHS survey students self-reported their responses to internationally standardized questions on a computer scannable answer sheet during one regular class period (33).

In HBSC, bullying was measured by the item: ‘How often have you been bullied at school in the past couple of months?’ The responses were: (1) I haven’t been bullied at school the past couple of months, (2) it has only happened once or twice, (3) 2 or 3 times a month, (4) about once a week, and (5) several times a week.^{30,33} The responses were dichotomized into: (1) never, (2) at least once. In the GSHS study, bullying was measured by the item: ‘During the past 30 days, on how many days were you bullied?’ The responses were: (A) 0 days, (B) 1 or 2 days, (C) 3 to 5 days, (D) 6 to 9 days, (E) 10 to 19 days (F) 20 to 29 days (G) all 30 days.³¹ The responses were dichotomized into: (1) 0 days, (2) at least 1 day. A full presentation of the measurements and response categories is presented in table 1.

WHAT WE FOUND

Table 2 presents basic data from the two surveys alphabetically by country and age-adjusted prevalence of bullying victimization based on the above dichotomizations. Figures 1 and 2 present country specific bullying victimization prevalence consecutively, for boys and girls.

We found large proportions of students reporting to be bullied at least sometimes within the past one or two months. On average 32.1 % of the children were bullied at school at least once within the past two months in countries involved in the HBSC study and 37.4 % of children were bullied at least one day with the past 30 days in countries involved in the GSHS study (table 2).

There was large variation in prevalence across countries. The lowest prevalence in the GSHS survey was observed in Tajikistan (7.1% for both boys and girls) and among HBSC countries in Sweden (16.0 % for boys and 14.6% for girls) and the Czech Republic (17.1% for boys and 14.2% for girls). The highest prevalence for boys in the GSHS survey was found in Zimbabwe (Bulawayo) (70.2%) and for girls in Zambia (67.1%). In the HBSC survey, Lithuania had the highest prevalence of bullying victimization (62.7% for boys and 64.4% for girls).

On average, prevalence was highest among boys (39.4% in the GSHS study and 33% in the HBSC study), but only slightly smaller among girls (33% in the GSHS and 29.2% in HBSC). In 40 of the 66 countries and regions, we found prevalence differences between boys and girls to be small (<5%), and in 15 victimization was more prevalent among girls. However, in the 26 countries or regions with gender prevalence differences larger than 5%, bullying was most prevalent among boys (see table 2). In four countries, the prevalence of bullying for boys was more than 10% higher than for girls (Belgium (French): 14.6%, Morocco: 16.3%, Zimbabwe (Bulawayo): 17.1% and Israel: 19.5%). Israel had the highest relative prevalence difference between boys and girls; the prevalence of bullying victimization for boys was almost double as high as for girls (39.9% vs 20.4%).

All African countries involved in the GSHS study, except Tanzania, had very high prevalence of bullying for both boys and girls. In six of the African countries more than every second boy were bullied, and in five of these countries this was also the case for girls. In

Boys

Figure 1. Age-adjusted prevalence of bullying among 13 to 15 year old boys from 66 countries and territories by country (percentage).

Girls

Figure 2. Age-adjusted prevalence of bullying among 13 to 15 year old girls from 66 countries and territories by country (percentage).

Other than the geographical patterns mentioned above, we found bullying prevalence to be largely unrelated to geographic area. For instance, among the Eastern Mediterranean countries included in the GSHS study, there were large prevalence differences between countries. In Egypt, 60.7% (average for boys and girls) of the 13-15 year old children were bullied, while in the Arab Emirates 21.0% were bully victims. And in Southern Europe, 44.8% of the Portuguese children were bullied, while this was the case for 24.3% of the Greek 13-15 year old children.

DISCUSSION

We found high prevalence of bullying in most of the 66 countries and territories studied. On average, every third 13-15 year old had been exposed to bullying within the past months. In only three countries, The Czech Republic, Sweden and Tajikistan, we found prevalence of bullying victimization to be under 20% for both genders. Even though, there were large differences in prevalence levels between countries, far too many children worldwide suffer from being victims of negative social, verbal or aggressive acts that are intended to hurt or degrade them.

In the Baltic countries and most of the African countries involved in the study, a majority of children are exposed to bullying. These numbers are worrying, and though especially the African countries have other major child public health issues of concern, efforts to reduce bullying should be made. School attendance in Africa is much lower than in most other regions of the world. The African countries included in this study all have between 57% (Zambia) and 85% (Botswana) of their children attending school, while most other countries in the study have more than 95% of their children attending primary education (34). Children that have the opportunity to attend school in these countries should not have their academic benefit, their well-being and their self worth damaged by high prevalence levels of bullying. Bullying on the scale found in African and Baltic countries is likely to affect every child, whether victim, offender or bystanders.

However, our study demonstrates that bullying is not only an issue for the countries mentioned above. Within all geographical regions studied, we found countries with high and countries with relatively low prevalence of bullying, and no obvious pattern to explain the variance. Countries, that would be reckoned to have approximately the same ability and resources to create healthy and democratic work environments for children, showed very different prevalence levels. For instance, in Sweden prevalence of bullying is low (15.3%), while in Denmark, another Scandinavian welfare state with much the same opportunities for families, schools, teachers and children, bullying prevalence was almost twice as high (29.6%). In Spain and Portugal, that are countries with geographical and cultural similarities, bullying prevalence is 25.6% and 44.8%, respectively. And despite the very high bullying prevalence in all other African countries in the study, only every fourth child in Tanzania has been a victim of bullying the past month (27.8%). Factors as knowledge, policies and interventions that may explain these international differences, should be explored and utilized to create policies and interventions in countries that have higher prevalence of bullying, despite possessing the same opportunities.

The strengths of this study are the use of two international surveys, with large random school samples taken from a wide variety of geographical and cultural settings. For both
